# PL HOMOLOGY 3-SPHERES AND TRIANGULATIONS OF MANIFOLDS 

## Ronald J. Stern ${ }^{1}$

One of the least understood but important groups arising in geometric topology is $\theta_{3}^{\mathrm{H}}$, the abelian group obtained from the set of oriented 3-dimensional PL homology spheres using the operation of connected sum, modulo those which bound acyclic PL 4-manifolds.

In this paper we will show how the group $\theta_{3}^{H}$ and the following theorem of Rohlin play an important role in triangulating topological manifolds.
V. A. Rohlin Signature Theorem ([4], [8], [12], [15]). Every closed oriented smooth 4 -manifold $\mathrm{M}^{4}$ whose second Stiefel-Whitney class vanishes has signature $\sigma(M) \in \mathrm{Z}$ divisible by 16 .

By classical smoothing theory the same theorem holds for PL 4-manifolds. However, the theorem is an important undecided result for topological 4-manifolds.

Given a PL homology 3 -sphere $H^{3}$, then $H^{3}$ bounds a parallelizable PL 4-manifold $W^{4}$. Let $\alpha\left(H^{3}\right) \in Z_{2}$ be the Kervaire-Milnor-Rohlin invariant given by

$$
\alpha\left(\mathrm{H}^{3}\right)=\alpha\left(\bar{W}^{4}\right) / 8(\bmod 2)
$$

where $\bar{W}^{4}$ is the closed (polyhearal) homology 4-manifold $\bar{W}^{4}=W^{4} \quad \underset{H^{3}}{U} \mathrm{cH}^{3}$. That $\sigma\left(\bar{W}^{4}\right)$ is divisible by 8 follows from the fact that the cup-product pairing of $\bar{W}^{4}$ is an even

[^0]quadratic form (see [14]). Also, an application of Rohlin's theorem and the additivity properties of the signature show that $\alpha\left(H^{3}\right)$ is independent of the bounding parallelizable manifold $W^{4}$, and in fact $\alpha$ determines a well-defined homomorphism $\alpha: \theta_{3}^{\mathrm{H}} \rightarrow Z_{2}$.

The classical example of a PL homology 3-sphere is the Poincaré homology 3 -sphere $H^{3}=\operatorname{SO}(3) / A_{5}$, where $A_{5}$ is the even permutation group on five objects $=$ the 60 orientation preserving symmetries of the dodecahedron. In fact $\pi_{1}(X)=$ $\left\langle a, b \mid a^{3}=b^{5}=(a b)^{2}\right\rangle \neq 0$. Now $H^{3}$ is also the boundary of the Milnor plumbing $W^{4}$ of 8 copies of the unit tangent disk bundle of $\mathrm{s}^{2}$ according to the Dynkin diagram

(For this and other descriptions of $\mathrm{H}^{3}$ see [9]). It is then an excellent exercise for an algebraic topology class to show that $\sigma\left(\bar{W}^{4}\right)=8$, thus demonstrating that the homomorphism $\alpha: \theta_{3}^{H} \rightarrow Z_{2}$ is surjective.

We now have a short exact sequence

$$
0 \rightarrow \operatorname{ker}(\alpha) \rightarrow \theta_{3}^{H} \xrightarrow{\alpha} Z_{2} \rightarrow 0
$$

Not one concrete fact is known about $\theta_{3}^{H}$ other than the existence of the surjection $\alpha: \theta_{3}^{H} \rightarrow z_{2}$. For instance, it is not even known if $\theta_{3}^{\mathrm{H}}$ is finitely generated.

The importance of the group ker $(\alpha)$ is explained by

Theorem l. (Galewski-Stern [6], [7], T. Matumoto [13]). Let $\mathrm{M}^{\mathrm{m}}$ be a topological manifold with $\partial \mathrm{M}$ triangulated as a simplicial complex. If $\mathrm{m} \geq 6$, then there $i s$ an element $\tau(M) \in H^{5}(M, \partial M$; $\operatorname{ker}(\alpha))$ such that $\tau(M)=0$ if and only if
there is a simplicial triangulation K of M with $\mathrm{K} \mid \partial \mathrm{M}$ compatible with the given triangulation on $\partial \mathrm{M}$. Moreover, there are $\left|H^{4}(M, \partial M ; \operatorname{ker}(\alpha))\right|$ such triangulations on $M$ up to concordance rez 2 M .

Two triangulations $K_{o}$ and $K_{l}$ of $M$ are concordant rel $\partial M$ if there is a triangulation $K$ of $M \times I$ such that $K \mid(\partial M \times I)$ is compatible with the given triangulation on $\partial M \times I$ and such that $\mathrm{K} \mid \mathrm{M} \times\{\mathrm{i}\}$ is compatible with $\mathrm{K}_{\mathrm{i}}$ for $\mathrm{i}=0,1$.

It should be noted that a priori there are two obstructions in Theorem $l$ to triangulating $M$, but one of these obstructions vanish since

Theorem 2. (R. D. Edwards [3]). Let $H^{3}$ be any PL homology 3-sphere. Then $\mathrm{S}^{2} \mathrm{*H}^{3}=\Sigma^{3} \mathrm{H}^{3}$ is homeomorphic to $\mathrm{S}^{6}$.

The importance of even a little understanding of $\theta_{3}^{\mathrm{H}}$ is explained by

Corollary 3. (Galewski-Stern [6], [7], T. Matumoto [13]). If there is an element $\mathrm{x} \in 0_{3}^{\mathrm{H}}$ with $\alpha(\mathrm{x})=1$ and $2 \mathrm{x}=0$, then all topological m-manifolds, $\mathrm{m} \geq 6$ ( $\geq 7$ if $\partial M \neq \phi)$ can be triantulated as simplicial complexes.

This leads us to the following well-known conjectures.
Conjecture 1. The group $\theta_{3}^{H}$ contains an element of order two.

Conjecture 2. The group ker ( $\alpha$ ) is the zero group.

In the remainder of this paper we will first consider the relationship between the simplicial triangulation obstruction of Theorem 1 and the combinatorial triangulation
obstruction of Kirby-Siebenmann [10]. These results are implicit in [7]. We will then show how elements of $\theta_{3}^{H}$ yield exotic PL manifold structures on $I^{k} \times T^{n}, k+n \geq 5$, which are the standard PL structure on $\partial I^{k} \times T^{n}$, and how elements of ker( $\alpha$ ) yield possibly exotic simplicial manifold structures on $I^{k} \times T^{n}, k+n \geq 5$, which are the standard $P L$ manifold structure on $\partial I^{k} \times T^{n}$. Furthermore, we will demonstrate that the exotic PL manifold structures on $\mathrm{I}^{k} \times \mathrm{T}^{\mathrm{n}}$ are nonexotic when considered as simplicial manifold structures. Here, $T^{n}$ is the cartesian product of $S^{l} n$-times, and $I^{k}$ is the cartesian product of the unit interval k-times.

Recall the short exact sequence

$$
0 \rightarrow \operatorname{ker}(\alpha) \rightarrow \theta_{3}^{\mathrm{H}} \xrightarrow{\alpha} \mathrm{Z}_{2} \rightarrow 0
$$

and the resulting Bockstein exact coefficient sequence

$$
\cdots \rightarrow H^{4}(M ; \underset{3}{H}) \xrightarrow[\rightarrow]{\alpha} H^{4}\left(M ; Z_{2}\right) \xrightarrow{\beta} H^{5}(M ; \operatorname{ker}(\alpha)) \rightarrow \cdots
$$

If $M$ is a polyhedral homology m-manifold, there is an element $r(M) \in H^{4}\left(M ; \theta_{3}^{H}\right)$ such that $r(M)=0$ if and only if there is a PL m-manifold $N$ and a PL acyclic map $f: N \rightarrow M$ (see [l], [2], [11]). If $M$ is also a topological manifold, let $\Delta(M) \in H^{4}\left(M ; Z_{2}\right)$ denote the Kirby-Siebenmann obstruction to putting a PL manifold structure on M [10]. Theorem ll.l of [7] shows that

$$
\begin{equation*}
\alpha_{\star} r(M)=\Delta(M) \tag{4}
\end{equation*}
$$

Note that this identifies $\Delta(M)$ as a simplicial cohomology class in the case that $M$ has a simplicial triangulation $K$. For then $\Delta(M)$ is represented by the cocycle $\alpha$ ': $C_{4}(M) \rightarrow Z_{2}$, where $C_{4}(M)$ is the free abelian group generated by the dual 4 -cells $e_{\sigma}^{4}$ of the (m-4)-simplices $\sigma$ of $K$ and $\alpha^{\prime}\left(e_{\sigma}^{4}\right)=$ $\alpha(\operatorname{link}(\sigma, K)) . \quad$ In particular, a topological m-manifold M,
$m \geq 5(\geq 6$ if $\partial M \neq \phi)$ has a $P L$ manifold structure if and only if there is a simplicial triangulation $K$ of $M$ such that the Kervaire-Milnor-Rohlin invariant of every 3-dimensional link of K is zero.

Since the obstruction to putting a PL manifold structure on a topological manifold $M$ and the obstruction to putting a simplicial manifold structure on M are lifting obstructions, standard obstruction theory shows that

$$
\begin{equation*}
\beta \Delta(M)=\tau(M) \tag{5}
\end{equation*}
$$

Furthermore, we have by Corollary 12.5 of [7] that if $\beta_{\star}: H^{4}\left(M ; Z_{2}\right) \rightarrow H^{5}(M ; Z)$ is the integral Bockstein homomorphism, then $\beta_{\star} \Delta(M)=0$ implies that $\tau(M)=0$.

Now to the construction of exotic triangulations on $I^{k} \times T^{n}, k+n \geq 5$. Let $S_{P L}\left(I^{k} \times T^{n}, \partial\right)$ denote the set of concordance (hence isotopy) classes of PL manifold structures on $I^{k} \times T^{n}$ extending the standard $P L$ manifold structure on $\partial I^{k} \times T^{n}$. Similarly, let $S_{T R I}\left(I^{k} \times T^{n}, \partial\right)$ denote the set of concordance classes of simplicial manifold structures on $I^{k} \times T^{n}$ extending the standard $P L$ manifold structure on $\partial I^{k} \times T^{n}$. There is a natural map $S_{P L}\left(I^{k} \times T^{n}, \partial\right) \rightarrow$ $S_{T R I}\left(I^{k} \times T^{n}, \partial\right)$. By the work of Kirby-Siebenmann [10], $\left|S_{P L}\left(I^{k} \times T^{n}, \partial\right)\right|=\left|H^{3-k}\left(T^{n} ; Z_{2}\right)\right|$ for $k+n \geq 5$; and by Theorem 1, $\left|S_{T R I}\left(I^{k} \times T^{n}, \partial\right)\right|=\left|H^{4-k}\left(T^{n} ; \operatorname{ker}(\alpha)\right)\right|$ for $k+n \geq 6$. Our goal is to construct non-trivial elements of $S_{P L}\left(I^{k} \times T^{n}, \partial\right)$ and $S_{T R I}\left(I^{k} \times T^{n}, \partial\right)$ and show that the natural map $S_{P L}\left(I^{3} \times T^{n}, \partial\right) \rightarrow S_{T R I}\left(I^{3} \times T^{n}, \partial\right)$ is the zero map for $n \geq 2$.

Let $H^{3}$ be a PL homology 3-sphere and let $F^{3}=H^{3}-$ int $I^{3}$. Then $F^{3} \times I^{n}$ has as boundary a $P L$ homology
$(\mathrm{n}+2)$-sphere $\mathrm{H}^{\mathrm{n}+2}$. Hence, by doing surgery on the interior of the parallelizable manifold $F^{3} \times I^{n}$ we have that $H^{n+2}$ bounds a contractible $\operatorname{PL}(\mathrm{n}+3)$-manifold $\mathrm{P}^{\mathrm{n}+3}$ if $\mathrm{n} \geq 2$. By identifying the $I^{n}$ factor in $\partial P^{n+3}=H^{n+2}=\partial\left(F^{3} \times I^{n}\right)$ so as to get $T^{n}$, we have a PL ( $n+3$ ) -manifold $M^{n+3}$ with boundary $S^{2} \times T^{n}$. Note that $M^{n+3}$ is homotopy equivalent rel $\partial M^{n+3}$ to $I^{3} \times T^{n}$. Since any manifold which is homotopy equivalent to $I^{k} \times T^{n}$ rel $a, k+n \geq 5$, is homeomorphic to $I^{k} \times T^{n}$ rel $\partial$ [16], we have that $M^{n+3}$ is homeomorphic to $I^{3} \times T^{n}$ rel $\partial$. The image of the PL manifold structure on $\mathrm{M}^{\mathrm{n}+3}$ under this homemorphism yields a PL manifold structure $\Gamma_{H} 3$ on $I^{3} \times T^{n}$ extending the standard $P L$ manifold structure on $\partial I^{3} \times T^{n}$, hence determines an element $\left[\Gamma_{H^{3}}\right] \in S_{P L}\left(I^{3} \times T^{n}, \partial\right)$.

Theorem 6. $\left[\Gamma_{H^{3}}\right]=0$ if and only if $\alpha\left(\mathrm{H}^{3}\right)=0$. Furthermore, the natural map $\mathrm{Z}_{2} \cong S_{\mathrm{PL}}\left(\mathrm{I}^{3} \times \mathrm{T}^{\mathrm{n}}, \partial\right) \rightarrow S_{\mathrm{TRI}}\left(\mathrm{I}^{3} \times \mathrm{T}^{\mathrm{n}}, \partial\right) \cong$ $\mathrm{n} \operatorname{ker}(\alpha)$ is the aero map.

Proof. Let $M^{n+3}$ be as above and let $h: M^{n+3} \rightarrow I^{3} \times T^{n}$ be a homeomorphism which is the identity over $\partial I^{3} \times T^{n}$. Attach a copy of $\mathrm{I}^{3} \times \mathrm{T}^{\mathrm{n}}$ to $\mathrm{M}^{\mathrm{n}+3}$ along $\partial \mathrm{M}^{\mathrm{n}+3}$ to obtain a PL manifold $M^{\prime}$ homeomorphic to $S^{3} \times T^{n}$. Note that $M^{\prime}$ bounds $Q^{n+4}=\left(\mathrm{CH}^{3} \times \mathrm{T}^{\mathrm{n}}\right) \cup\{$ handles $\}$. By Theorem $2 Q^{\mathrm{n}+4}$ is simplicially triangulated topological manifold which is an s-cobordism between $M^{n+3}$ and $I^{3} \times T^{n}$ rel $\partial$. By the observations following (4), $\mathrm{CH}^{3} \times \mathrm{T}^{\mathrm{n}}$ possesses a PL manifold structure extending the natural one on $H^{3} \times T^{n}$ if and only if $\alpha\left(H^{3}\right)=0$. This also follows from Theorem $C$ of [17].

Let $Q_{*}^{n+4}$ be the topological manifold obtained by adjoining the mapping cylinder of $h$ to $Q^{n+4}$ along $M^{n+3}$. Then
$Q_{*}^{n+4}$ is homotopy equivalent to $I^{4} \times T^{n}$ rel $\partial Q_{*}^{n+4}=S^{3} \times T^{n}$, hence $Q_{*}^{n+4}$ is homeomorphic to $I^{4} \times T^{n}$ rel $\partial I^{4} \times T^{n}$. This homeomorphism induces a simplicial manifold structure $\sum_{H} 3$ on $I^{4} \times T^{n}$ and a simplicial manifold concordance between $\Gamma_{H^{3}}$ and the standard structure on $I^{3} \times T^{n}$. It now follows that $\left[\Gamma_{H^{3}}\right]=0$ if and only if $\alpha\left(H^{3}\right)=0$ and that $S_{P L}\left(I^{3} \times T^{n}, \partial\right) \rightarrow S_{T R I}\left(I^{3} \times T^{n}, \partial\right)$ is the zero map for $n \geq 2$.

Perhaps Theorem 6 morally justifies Conjecture 2 above.
Note that in the proof of Theorem 6, the simplicial manifold structure $\Sigma_{H} 3$ on $I^{4} \times T^{n}$ can be assumed to be the standard PL manifold structure on $\partial \mathrm{I}^{4} \times \mathrm{T}^{\mathrm{n}}$ if $\alpha\left(\mathrm{H}^{3}\right)=0$, for we can assume that $h: M^{n+3} \rightarrow I^{3} \times T^{n}$ is a PL homeomorphism. There results for each PL homology 3-sphere $H^{3}$ with $\alpha\left(H^{3}\right)=0$ an element $\left[\Sigma_{H^{3}}\right] \in S_{T R I}\left(I^{4} \times T^{n}, \partial\right) \cong \operatorname{ker}(\alpha)$.

Theorem 7. Let $\mathrm{H}^{3}$ and $\overline{\mathrm{H}}^{3}$ be PL homology 3-spheres with $\alpha\left(\mathrm{H}^{3}\right)=\alpha\left(\overline{\mathrm{H}}^{3}\right)=0$. Then $\left[\Sigma_{\mathrm{H}^{3}}\right]=\left[\Sigma_{\overline{\mathrm{H}}^{3}}\right]$ if and only if there is a PL homology cobordism between $\mathrm{H}^{3}$ and $\overline{\mathrm{H}}^{3}$.

Proof. Recall that $\Sigma_{H 3}$ is the simplicial manifold structure on $\mathrm{I}^{4} \times \mathrm{T}^{\mathrm{n}}$ induced by a simplicial manifold structure on the topological manifold $Q^{n+4}=\left(\mathrm{cH}^{3} \times \mathrm{T}^{\mathrm{n}}\right) \cup$ \{handles\}. Similarly, $\Sigma_{\bar{H} 3}$ is induced by a simplicial manifold structure on the topological manifold $\bar{Q}^{n+4}=\left(\bar{H}^{3} \times T^{n}\right) \cup\{$ handles $\}$. Let $X^{4}$ be a PL homology cobordism between $H^{3}$ and $\bar{H}^{3}$. Now $H^{4}=\mathrm{CH}^{3} \cup \mathrm{X}^{4} \cup \mathrm{c} \bar{H}^{4}$ is a polyhedral homology manifold having the homology of $S^{4}$ and with $H^{4} \times R^{2}$ a topological manifold. By Theorem 1.4 of [7], $\mathrm{CH}^{4} \times \mathbf{R}^{2}$ is a topological manifold so that $P^{n+5}=\left(Q^{\mathrm{n}+4} \times \mathrm{I}\right) \cup\left(\mathrm{CH}^{4} \times \mathrm{T}^{\mathrm{n}}\right) \cup\left(\bar{Q}^{\mathrm{n}+4} \times \mathrm{I}\right)$ is a
simplicially triangulated topological manifold. By attaching PL handles to $\mathrm{X}^{4} \times \mathrm{T}^{\mathrm{n}} \subset \mathrm{P}^{\mathrm{n}+5}$ we obtain a simplicially triangulated topological manifold $Y^{n+5}=\left(Q^{n+4} \times I\right) U\left(\mathrm{CH}^{4} \times T^{n}\right)$ $U$ \{handles\} $U\left(\bar{Q}^{n+4} \times I\right)$ homotopy equivalent to $I^{5} \times T^{n}$. An application of the PL s-cobordism theorem to the boundary PL s-cobordism in $Y^{n+5}$ between $\partial Q^{n+4}$ and $\partial \bar{Q}^{n+4}$, each of which we identify with $\partial \mathrm{I}^{4} \times \mathrm{T}^{\text {n }}$ via a PL homeomorphism, yields a simplicially triangulated topological manifold $Y_{*}^{n+5}$ homotopy equivalent to $I^{5} \times T^{n}$ and with $\partial Y_{*}^{n+5}=Q^{n+4} U$ $S^{3} \times T^{n} \times I \cup \bar{Q}^{\mathrm{n}+4}$. There results a concordance between $\Sigma_{H^{3}}$ and $\Sigma_{\bar{H}^{3}}$.

Conversely, suppose $\left[\Sigma_{H^{3}}\right]=\left[\Sigma_{\bar{H}} 3\right]$. Then there is a simplicially triangulated topological manifold $W^{n+5}$ with $\partial W^{n+5}=Q^{n+4} \cup S^{3} \times T^{n} \times I \cup Q^{n+4}$ and with a homeomorphism $\mathrm{f}: \mathrm{W}^{\mathrm{n}+5} \rightarrow \mathrm{I}^{4} \times \mathrm{T}^{\mathrm{n}} \times \mathrm{I}$ which is PL over $\partial \mathrm{I}^{4} \times \mathrm{T}^{\mathrm{n}} \times \mathrm{I}$. Let $\pi: \mathrm{CH}^{3} \times \mathrm{T}^{\mathrm{n}} \rightarrow \mathrm{I}^{4} \times \mathrm{T}^{\mathrm{n}}$ and $\bar{\pi}: \mathrm{CH}^{3} \times \mathrm{T}^{\mathrm{n}} \rightarrow \mathrm{I}^{4} \times \mathrm{T}^{\mathrm{n}}$ be homology equivalences which fiber over $\mathrm{T}^{\mathrm{n}}$. There is no obstruction to extending $\pi$ and $\bar{\pi}$ to a homotopy equivalence $p: W^{n+5} \rightarrow I^{4} \times$ $T^{n} \times I$, with $p \mid f^{-1}\left(\partial I^{4} \times T^{n} \times I\right): f^{-1}\left(\partial I^{4} \times T^{n} \times I\right) \rightarrow \partial I^{4} \times$ $\mathrm{T}^{\mathrm{n}} \times \mathrm{I}$ a homotopy equivalence. Homotope p so that $p \mid f^{-1}\left(\partial I^{4} \times T^{n} \times I\right)$ is $P L$ transverse to $S^{3} \times(p t) \times$.$I .$ There results a PL cobordism $X^{4}$ between $H^{3}$ and $\bar{H}^{3}$. There is a transversality theory for maps of homology manifolds provided that the target is a PL manifold (Theorem 3.7 of [5]). So homotope $p$ rel $f^{-1}\left(\partial I^{4} \times T^{n} \times I\right)$ to be homology transverse to $I^{4} \times$ (pt.) $\times I$. There results a homology manifold cobordism $X^{5}$ between $c H^{3}$ and $c \bar{H}^{3}$ extending $X^{4}$. Now $\partial X^{5}$ bounds the homology manifold $X^{5}$, so that $r\left(\partial X^{5}\right)=0$. But the only non PL 3-sphere links of $\partial X^{5}$ are $H^{3}$ and $\bar{H}^{3}$. Thus $H^{3} \#-\bar{H}^{3}$
bounds a PL acyclic 4-manifold, hence $H^{3}$ and $\bar{H}^{3}$ are PL homology cobordant.

To construct non-trivial elements of $S_{P L}\left(I^{k} \times T^{n}, \partial\right) \cong$ $H^{3-k}\left(T^{n} ; Z_{2}\right), k+n \geq 5$, take the non-trivial element of $S_{P L}\left(I^{3} \times T^{n-k}, \partial\right)$ constructed above and identify the opposite ends of $k$ - interval factors of $I^{3}$ to derive a non-trivial element of $S_{P L}\left(I^{k} \times T^{n}, \partial\right)$. Note that these elements are trivial when considered as elements of $S_{T R I}\left(I^{k} \times T^{n}, \partial\right)$. Similarly one constructs (possibly) non-trivial elements of $S_{T R I}\left(I^{k} \times T^{n}, \partial\right) \cong H^{4-k}\left(T^{n} ; \operatorname{ker}(\alpha)\right), k+n \geq 6$, from the elements of $S_{T R I}\left(I^{4} \times T^{n}, \partial\right)$ constructed above.
