A *continuum* is a compact connected metric space.

A continuum is *1-dimensional* if for every  $\epsilon > 0$  there exists a finite open cover  $\mathcal{U}$  of  $X$  with mesh less than  $\epsilon$  such that every  $x \in X$  is contained in at most 2 elements of  $\mathcal{U}$ .

A *continuum* is a compact connected metric space.

A continuum is *1-dimensional* if for every  $\epsilon > 0$  there exists a finite open cover  $\mathcal{U}$  of  $X$  with mesh less than  $\epsilon$  such that every  $x \in X$  is contained in at most 2 elements of  $\mathcal{U}$ .

Let  $\{X_i\}_{i=1}^{\infty}$  be a sequence of topological spaces. For each  $i$ , let  $f_i : X_{i+1} \rightarrow X_i$  be a continuous function called a *bonding map*. The collection  $\{X_i, f_i\}_{i=1}^{\infty}$  is called an *inverse system*. Each space  $X_i$  is called a *factor space* of the inverse system.

If each factor space is the same space  $X$  then the inverse system can be written as  $\{X, f_i\}_{i=1}^{\infty}$ . Likewise, if each bonding map is the same map  $f$ , then the inverse system can be written as  $\{X, f\}_{i=1}^{\infty}$ . Also, the inverse system  $\{X_i, f_i\}_{i=1}^{\infty}$  is sometimes written as

$$X_1 \xleftarrow{f_1} X_2 \xleftarrow{f_2} X_3 \dots X_{i-1} \xleftarrow{f_{i-1}} X_i \xleftarrow{f_i} \dots$$

Every inverse system  $\{X_i, f_i\}_{i=1}^{\infty}$  determines a topological space  $\hat{X}$  called the **inverse limit** of the system and is written  $\varprojlim \{X_i, f_i\}_{i=1}^{\infty}$ . The space  $\hat{X}$  is the subspace of the Cartesian product  $\prod_{i=1}^{\infty} X_i$  given by

$$\hat{X} = \varprojlim \{X_i, f_i\}_{i=1}^{\infty} = \{(x_i)_{i=1}^{\infty} \in \prod_{i=1}^{\infty} X_i \mid f_i(x_{i+1}) = x_i\}.$$

$\hat{X}$  has the subspace topology induced on it by  $\prod_{i=1}^{\infty} X_i$ . If  $\mathbf{x} = (x_i)_{i=1}^{\infty}$  and  $\mathbf{y} = (y_i)_{i=1}^{\infty}$  are two points of the inverse limit, we define distance to be

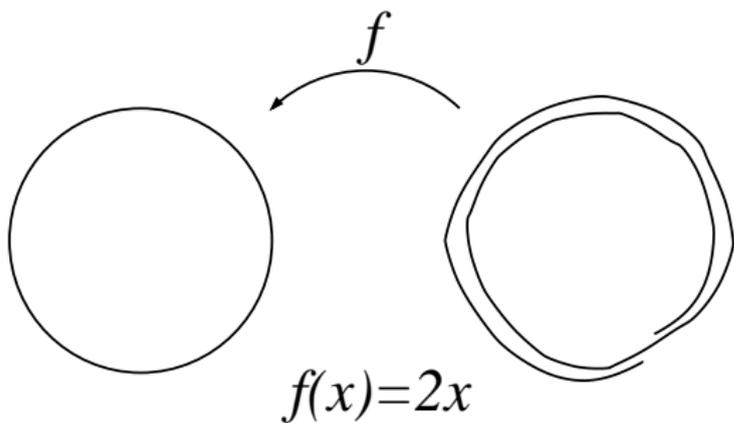

$$d(\mathbf{x}, \mathbf{y}) = \sum_{i=1}^{\infty} \frac{d_i(x_i, y_i)}{2^i},$$

where  $d_i$  is the metric on  $X_i$ .

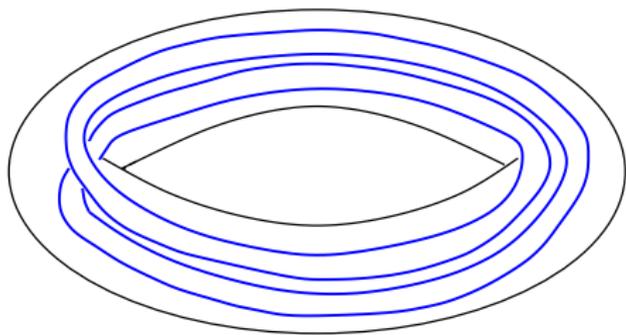

$\mathbf{x} = (x_i)_{i=1}^{\infty}$  is often called a **thread** of the inverse system.

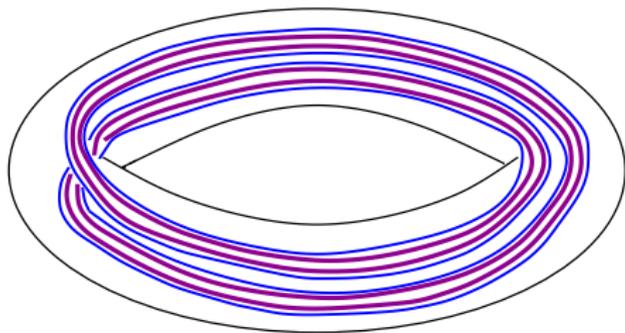

For example, let  $f : S \rightarrow S$  by  $f(x) = 2x(\text{mod}1)$  Then the dyadic solenoid  $\Sigma_2$  is given by

$$\Sigma_2 = \varprojlim \{S, f\}_{i=1}^{\infty} = \{(x_1, x_2, x_3, \dots) \mid f(x_{i+1}) = x_i\}.$$

$$X = \{ (x_1, x_2, x_3, \dots) \mid f_i(x_{i+1}) = x_i \}$$

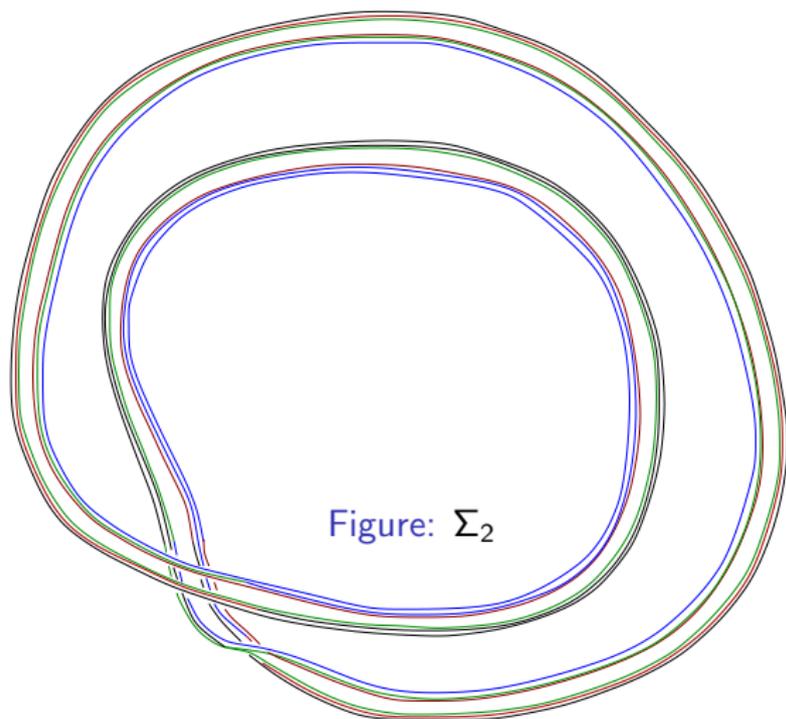

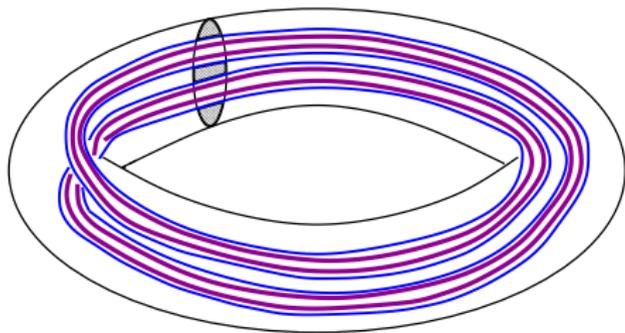

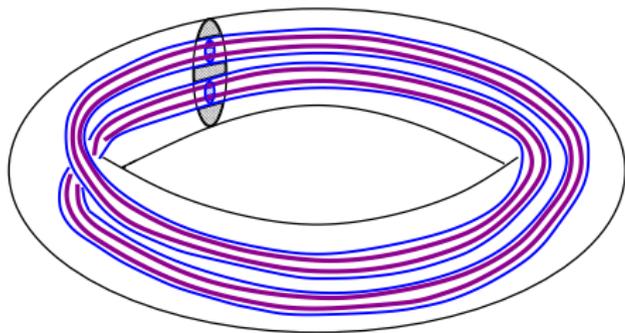

Figure:  $\Sigma_2$

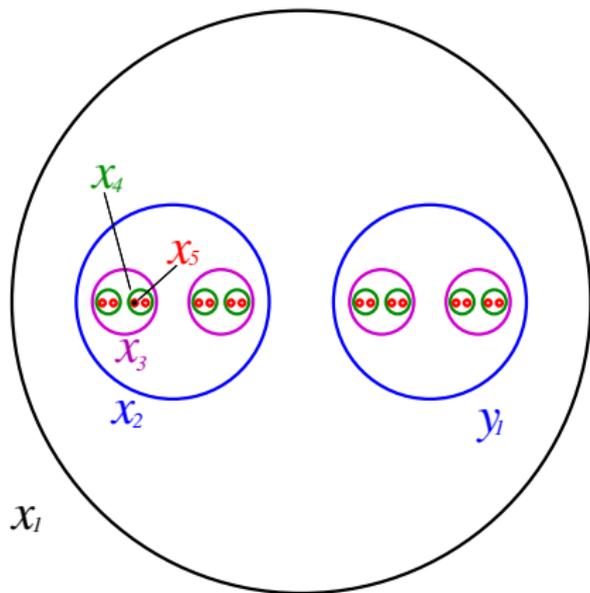

Figure:  $X = \{(x_1, x_2, x_3, \dots) \mid f_i(x_{i+1}) = x_i\}$ .

I will only be focusing on one-dimensional continua.

**Fact:** If each factor is one-dimensional then the inverse limit is one-dimensional.

**Fact:** Every one-dimensional continuum can be expressed as the inverse limits of graphs

# Shape Considerations

A connected graph  $G$  is *0-cyclic* if it contains no cycles, i.e., is a tree.

A connected graph  $G$  is *k-cyclic* if  $k$  is the smallest number edges  $\{e_1, \dots, e_k\}$  that must be removed from  $G$  so that there are no longer any cycles.

That is  $G - \{e_1, \dots, e_k\}$  is a *spanning tree* for  $G$ .

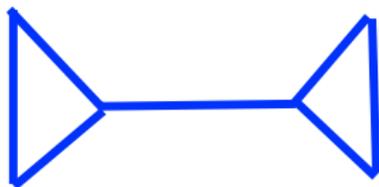

Figure: 2-cyclic graphs.

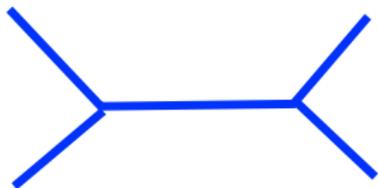

Figure: 2-cyclic graphs.

A continuum is

- ① *chainable* (also known as *arc-like*)
- ② *tree-like*
- ③ *G-like*
- ④ *k-cyclic*

if it is the inverse limit of a(n)

- ①  $\text{arc}(s)$
- ②  $\text{tree}(s)$
- ③ topological graph(s) homeomorphic to the same graph  $G$
- ④  $k$ -cyclic topological graph(s)

respectively.

A continuum is

- ① *chainable* (also known as *arc-like*)
- ② *tree-like*
- ③ *G-like*
- ④ *k-cyclic*

if it is the inverse limit of a(n)

- ① *arc(s)*
- ② *tree(s)*
- ③ *topological graph(s) homeomorphic to the same graph  $G$*
- ④ *k-cyclic topological graph(s)*

respectively.

Likewise,

A continuum is

- 1 *chainable* (also known as *arc-like*)
- 2 *tree-like*
- 3 *G-like*
- 4 *k-cyclic*

if for every  $\epsilon > 0$  there exist an open cover whose nerve is a(n)

- 1  $\text{arc}(s)$
- 2  $\text{tree}(s)$
- 3 topological graph(s) homeomorphic to the same graph  $G$
- 4 *k-cyclic* topological graph(s)

respectively.

# Dynamics

The primary motivation to study the necessary topology of continua that admit homeomorphisms with a particular “chaotic” properties.

In particular, I am interested in what conditions for the continuum to be

- ① indecomposable
- ② contain an indecomposable subcontinuum
- ③  $1/n$  indecomposable
- ④ if hereditarily decomposable, then what can be said about the topology

The primary motivation to study the necessary topology of continua that admit homeomorphisms with a particular “chaotic” properties.

In particular, I am interested in what conditions for the continuum to be

- ① indecomposable
- ② contain an indecomposable subcontinuum
- ③  $1/n$  indecomposable
- ④ if hereditarily decomposable, then what can be said about the topology

A continuum  $X$  is *decomposable* if it is the union of 2 of its **proper** subcontinua.

A continuum is *indecomposable* if it is not decomposable.

Equivalently,  $X$  is indecomposable if every **proper** subcontinuum is nowhere dense.

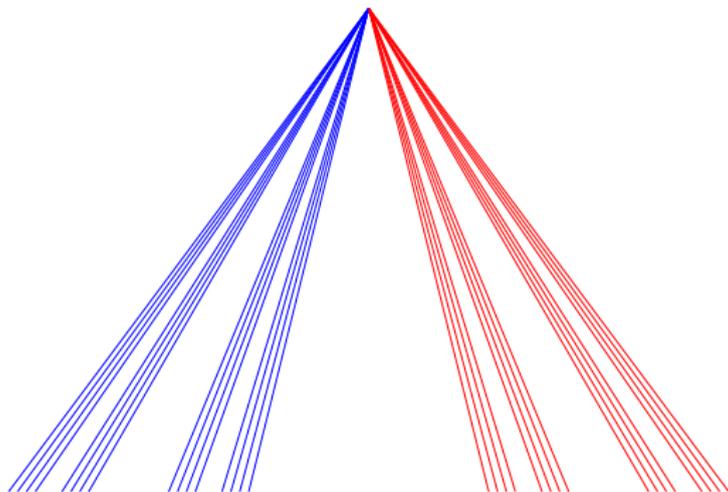

Figure: Decomposable

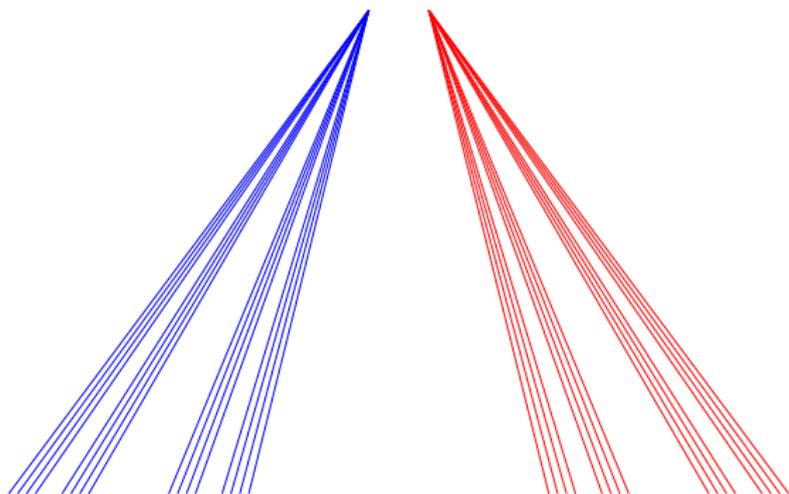

Figure: Decomposable

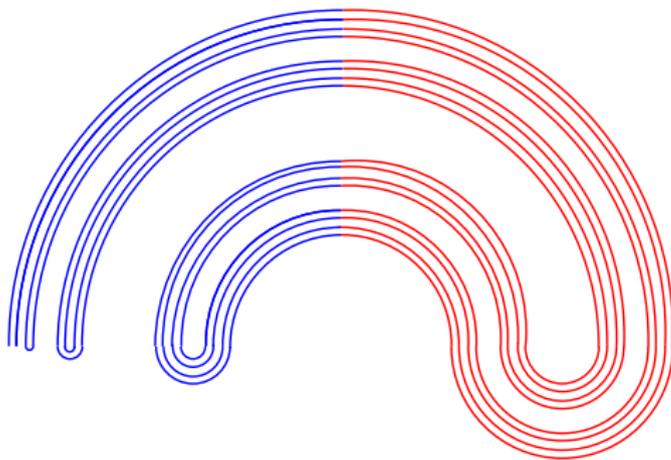

Figure: Indecomposable

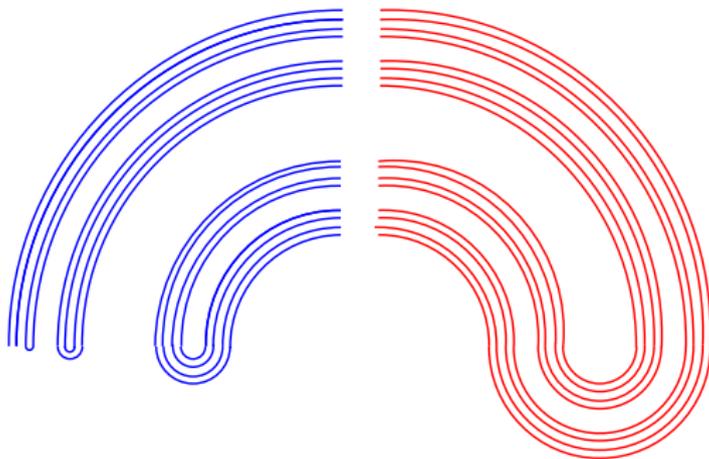

Figure: Indecomposable

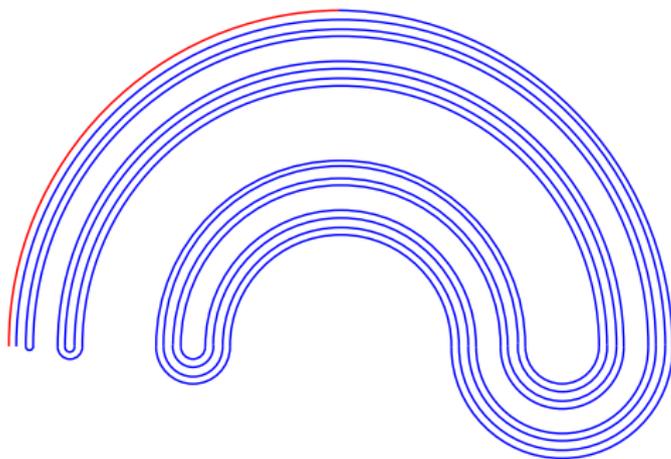

Figure: Indecomposable

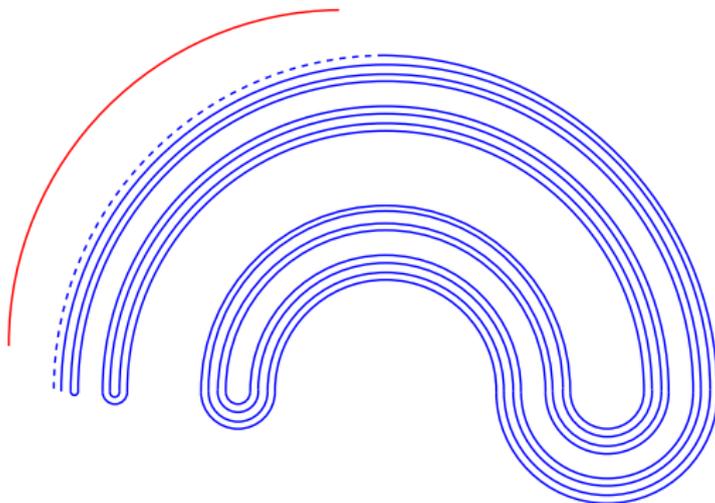

Figure: Indecomposable

A map  $f$  is *positively continuum-wise fully expansive* if for every  $\epsilon > 0$  and nondegenerate subcontinuum  $Y$ , there exists  $N = N(\epsilon, Y)$  such that  $d_H(f^n(Y), X) < \epsilon$  for all  $n \geq N$ .

A map  $f$  is *weakly positively continuum-wise fully expansive* if there exist a dense subset  $Z$  of the hyperspace of  $X$  such that for every  $\epsilon > 0$  and subcontinuum  $Y \in Z$ , there exists  $N = N(\epsilon, Y)$  such that  $d_H(f^n(Y), X) < \epsilon$  for all  $n \geq N$ .

Map  $f$  is *continuum-wise expansive* if there exists a  $c > 0$  such that for every nondegenerate subcontinuum  $Y \subset X$ , there is an  $n \in \mathbb{N}$  such that  $\text{diam}(f^n(Y)) \geq c$ .

A map  $f$  is *mixing* if for every open sets  $U, V$  of  $X^n$ , there exists an  $M$  such that  $f^m(U) \cap V \neq \emptyset$  for all  $m \geq M$ .

That is, if  $U$  is open, then  $d_H(f^n(U), X) \rightarrow 0$  as  $n \rightarrow \infty$ .

Map  $f$  is *continuum-wise expansive* if there exists a  $c > 0$  such that for every nondegenerate subcontinuum  $Y \subset X$ , there is an  $n \in \mathbb{N}$  such that  $\text{diam}(f^n(Y)) \geq c$ .

A map  $f$  is *mixing* if for every open sets  $U, V$  of  $X^n$ , there exists an  $M$  such that  $f^m(U) \cap V \neq \emptyset$  for all  $m \geq M$ .

That is, if  $U$  is open, then  $d_H(f^n(U), X) \rightarrow 0$  as  $n \rightarrow \infty$ .

## Theorem

If  $f : X \rightarrow X$  is a map of a continuum then:

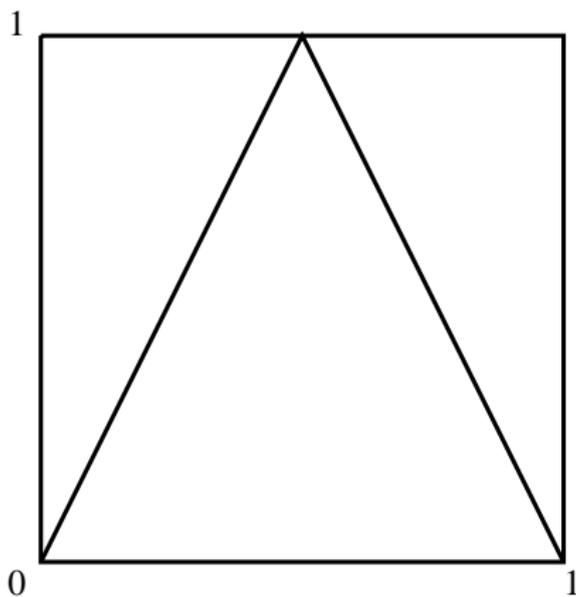

$f$  is fully continuum-wise expansive.

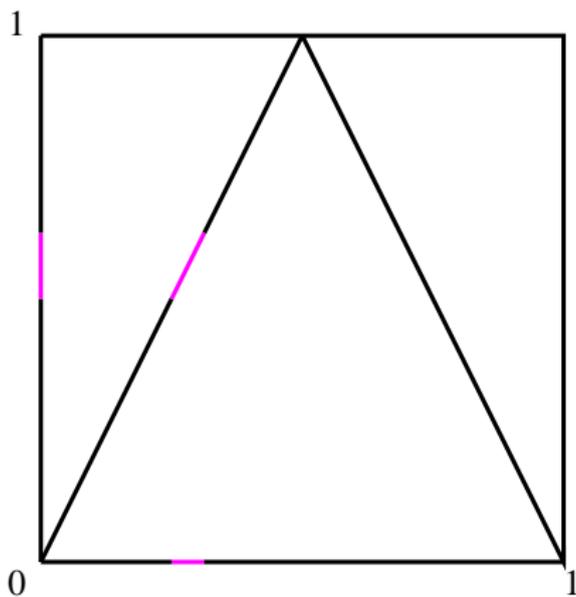

$f$  is weakly fully continuum-wise expansive.

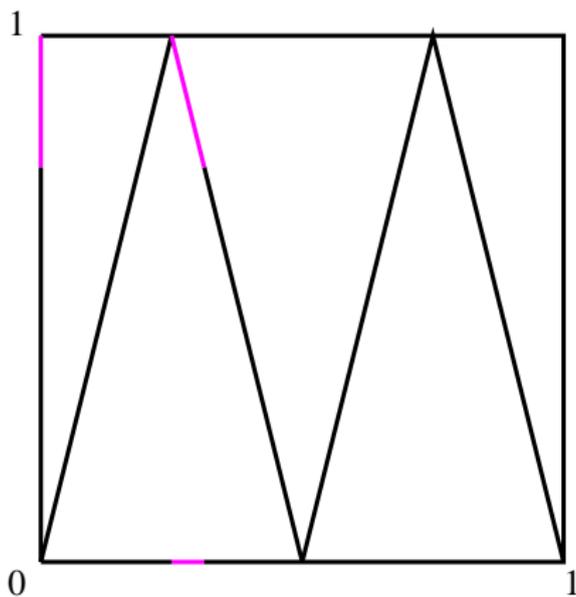

$f$  is mixing.

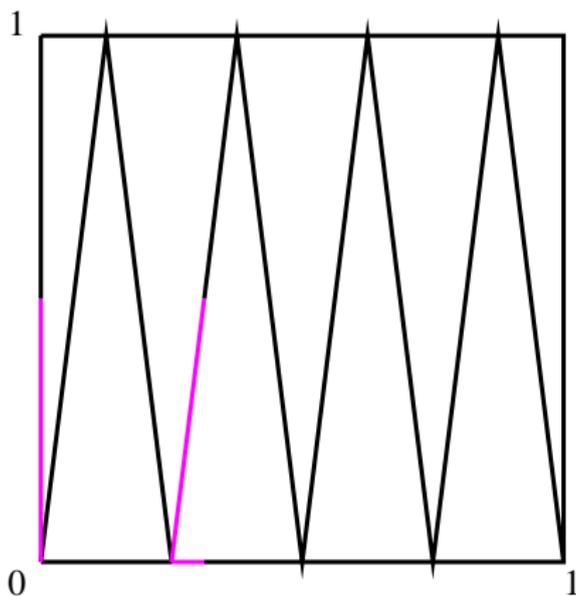

**Figure:** The tent map,  $T : [0, 1] \longrightarrow [0, 1]$ , is a positively continuum-wise fully expansive function.

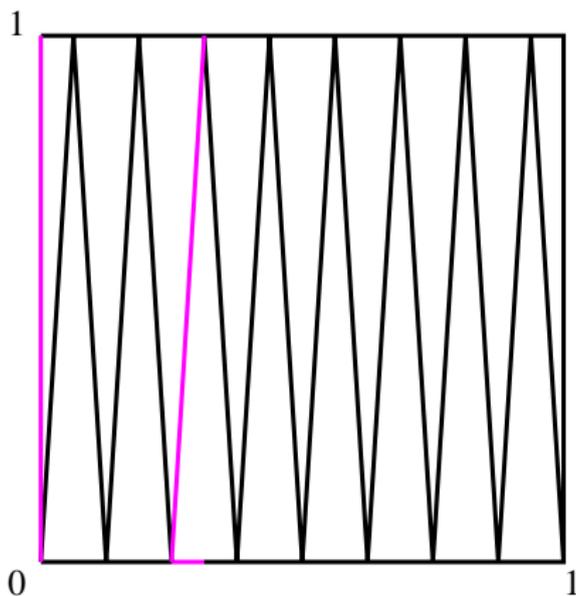

**Figure:** The tent map,  $T : [0, 1] \longrightarrow [0, 1]$ , is a positively continuum-wise fully expansive function.

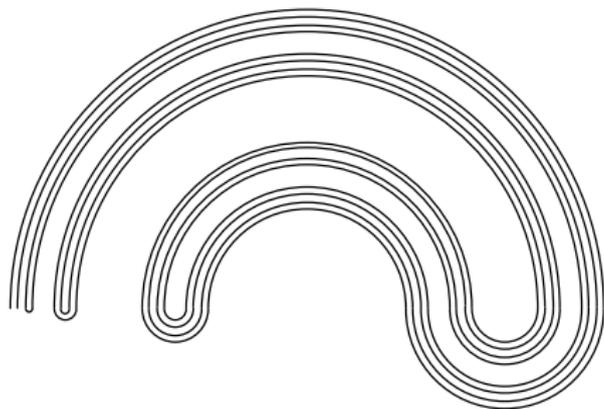

**Figure:** The tent map,  $T : [0, 1] \longrightarrow [0, 1]$ , is a positively continuum-wise fully expansive function.

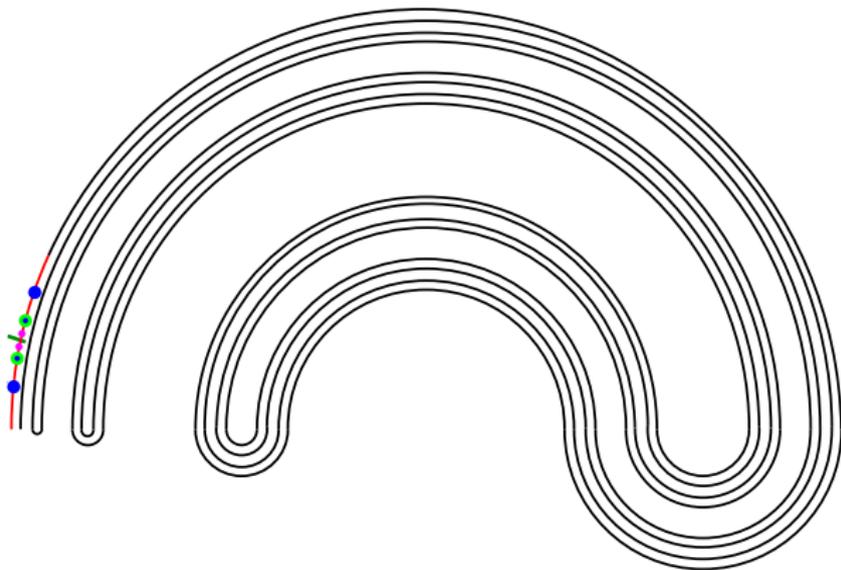

**Figure:** The tent map,  $T : [0, 1] \longrightarrow [0, 1]$ , is a positively continuum-wise fully expansive function.

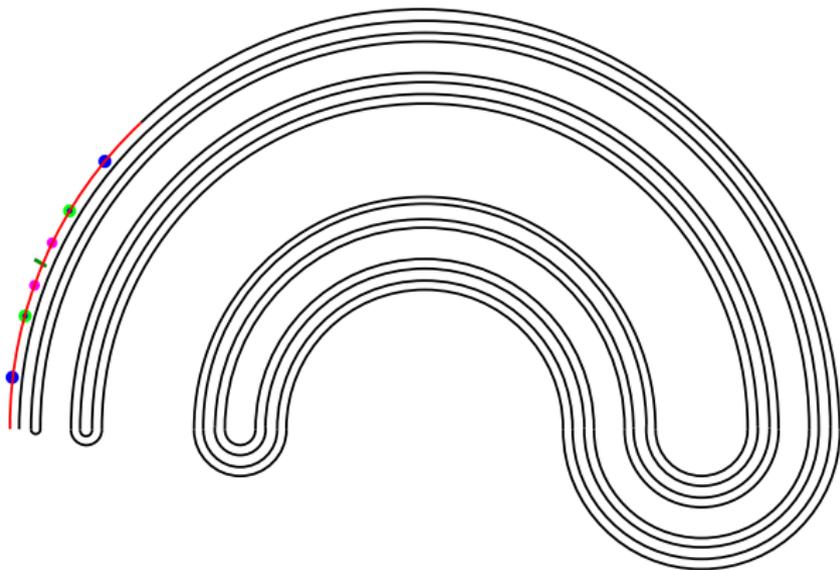

**Figure:** The tent map,  $T : [0, 1] \longrightarrow [0, 1]$ , is a positively continuum-wise fully expansive function.

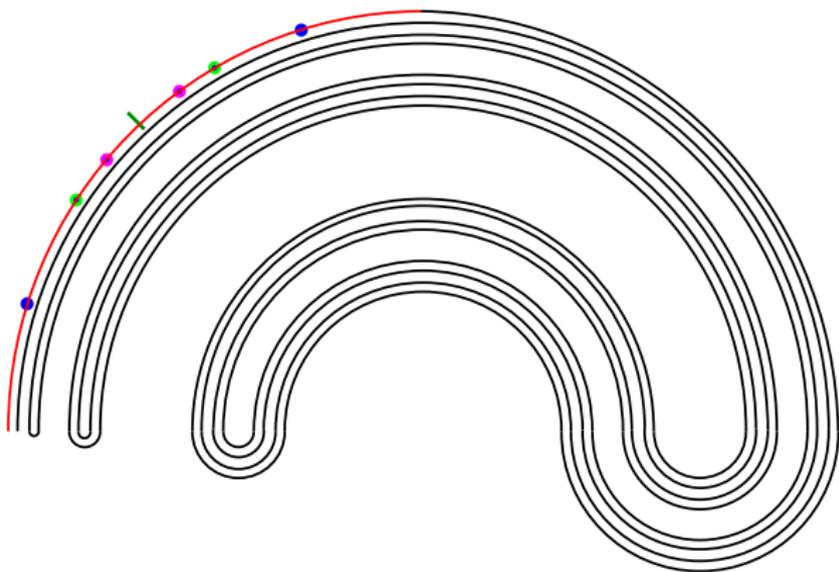

**Figure:** The buckhandle continuum is the inverse limit of the tent map:  
 $\varprojlim ([0, 1], T)$

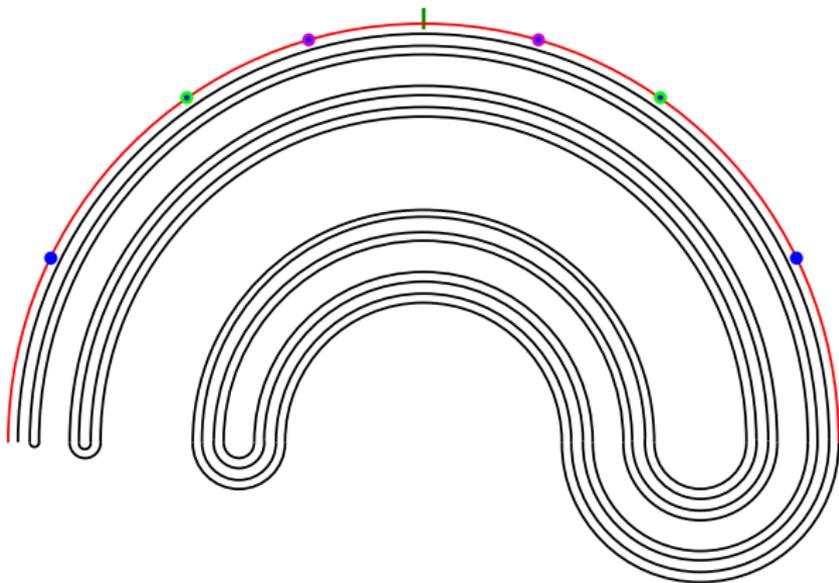

The shift of the tent map,  $\widehat{T}$ , is a positively continuum-wise fully expansive homeomorphism.

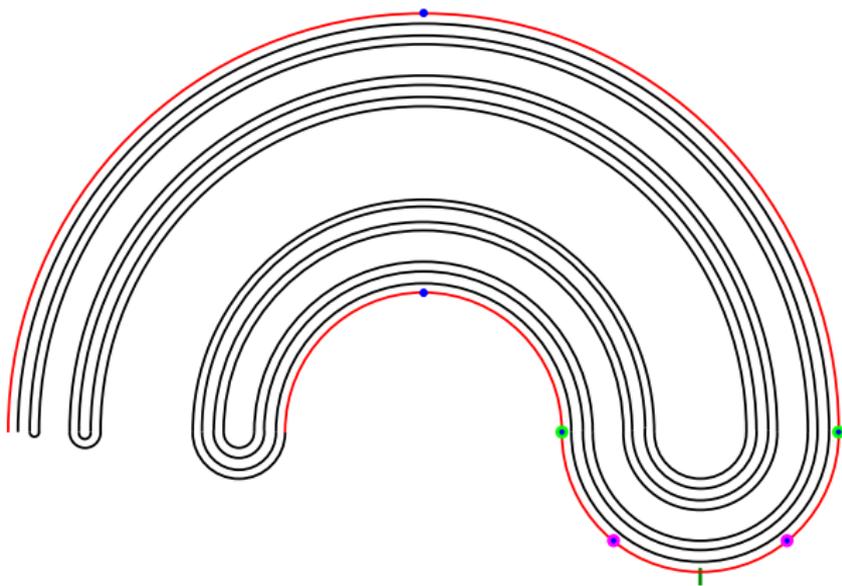

The shift of the tent map,  $\widehat{T}$ , is a positively continuum-wise fully expansive homeomorphism.

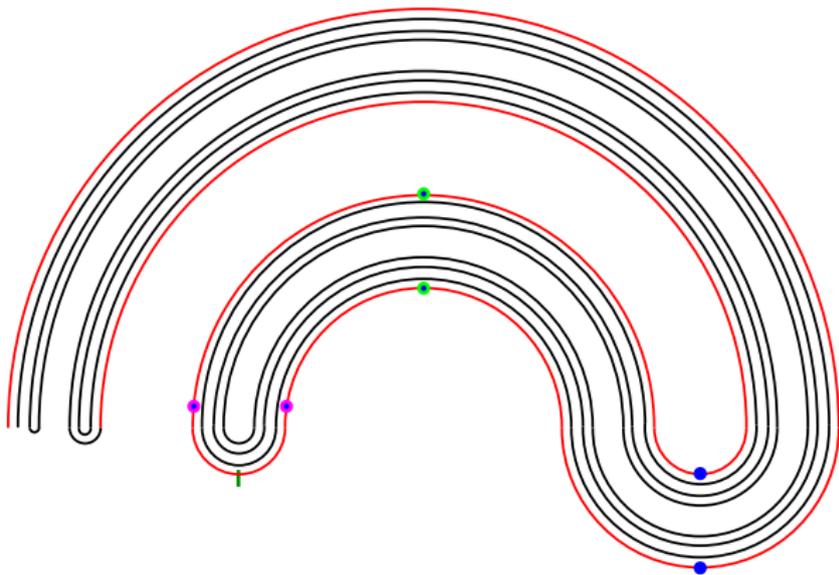

The shift of the tent map,  $\widehat{T}$ , is a positively continuum-wise fully expansive homeomorphism.

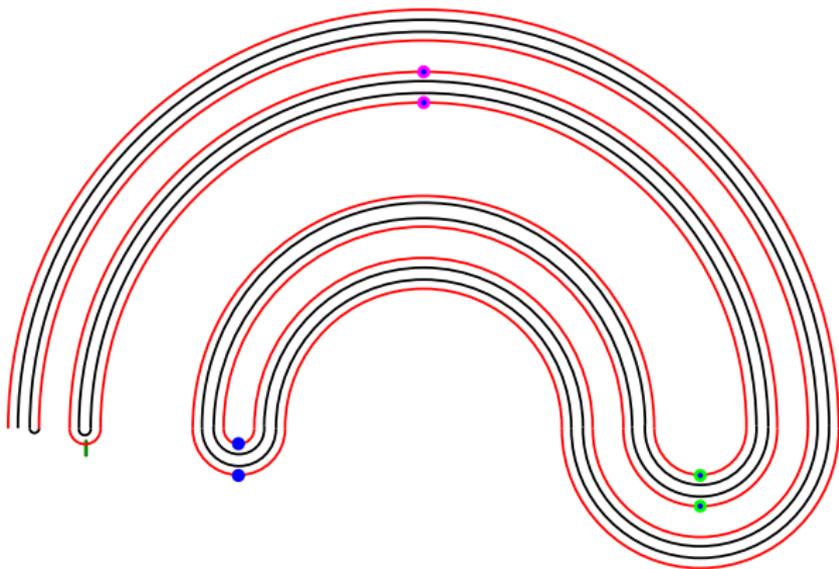

The shift of the tent map,  $\widehat{T}$ , is a positively continuum-wise fully expansive homeomorphism.

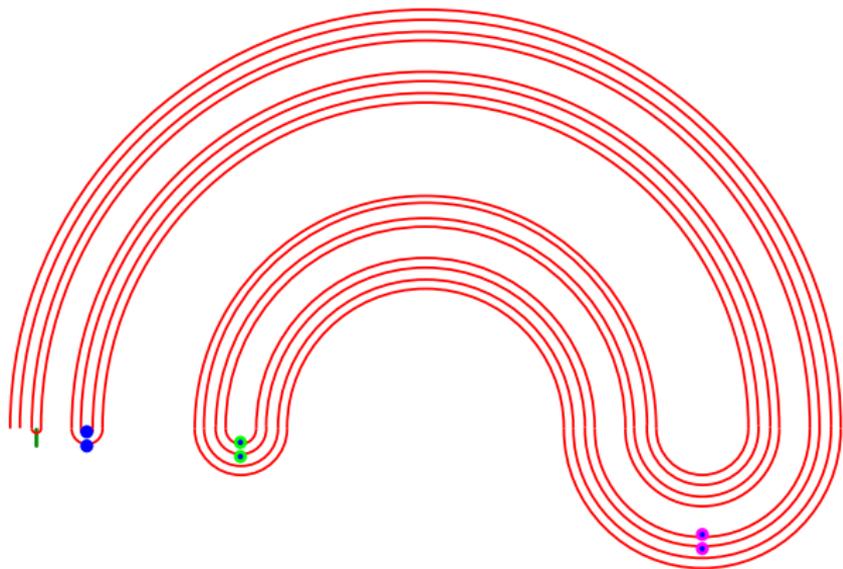

The shift of the tent map,  $\widehat{T}$ , is a positively continuum-wise fully expansive homeomorphism.

The shift of the tent map,  $\widehat{T}$ , is a positively continuum-wise fully expansive homeomorphism.

The shift of the tent map,  $\widehat{T}$ , is a positively continuum-wise fully expansive homeomorphism.

The shift of the tent map,  $\widehat{T}$ , is a positively continuum-wise fully expansive homeomorphism.

## Theorem

## Theorem

*(M,M,MV) If  $X$  is a  $G$ -like continuum that admits a mixing homeomorphism, then  $X$  is indecomposable.*

A continuum  $X$  is  $1/n$  indecomposable if whenever  $\{A_i\}_{i=1}^n$  are a collection of pairwise disjoint subcontinua, at least one of  $\{A_i\}_{i=1}^n$  has empty interior. Note:  $1/2$  indecomposable is also called *semi-indecomposable*.

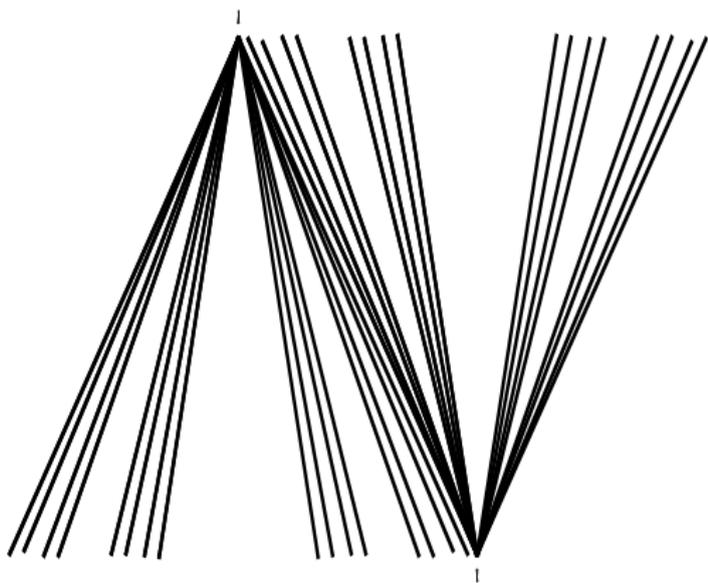

## Theorem

*(M,M,MV) If  $X$  is a  $G$ -like continuum that admits a mixing homeomorphism, then  $X$  is indecomposable.*

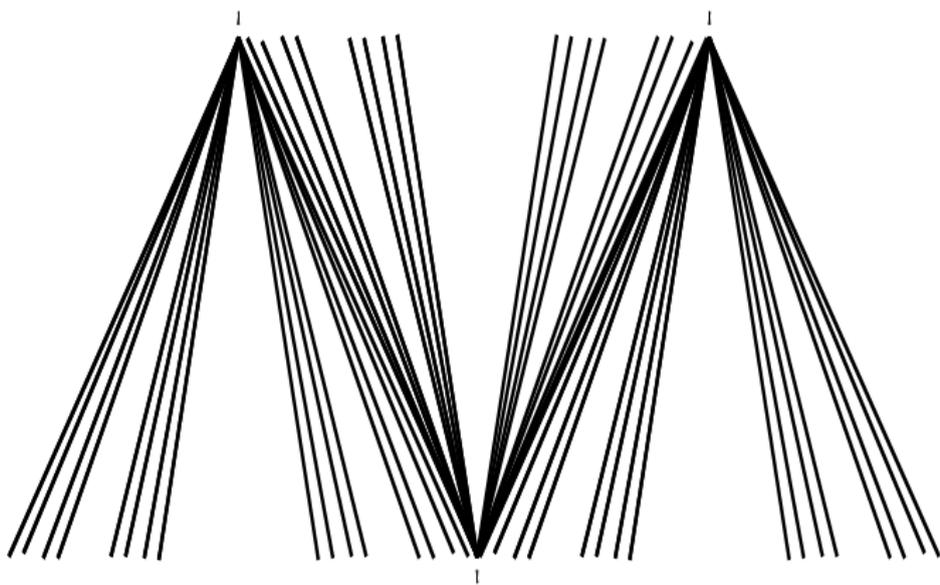

A continuum  $X$  is  $1/n$  indecomposable if whenever  $\{A_i\}_{i=1}^n$  are a collection of pairwise disjoint subcontinua, at least one of  $\{A_i\}_{i=1}^n$  has empty interior. Note:  $1/2$  indecomposable is also called *semi-indecomposable*.

The Cantor Fan is  $1/2$  or *semi*- indecomposable.

This is  $1/3$ -indecomposable.

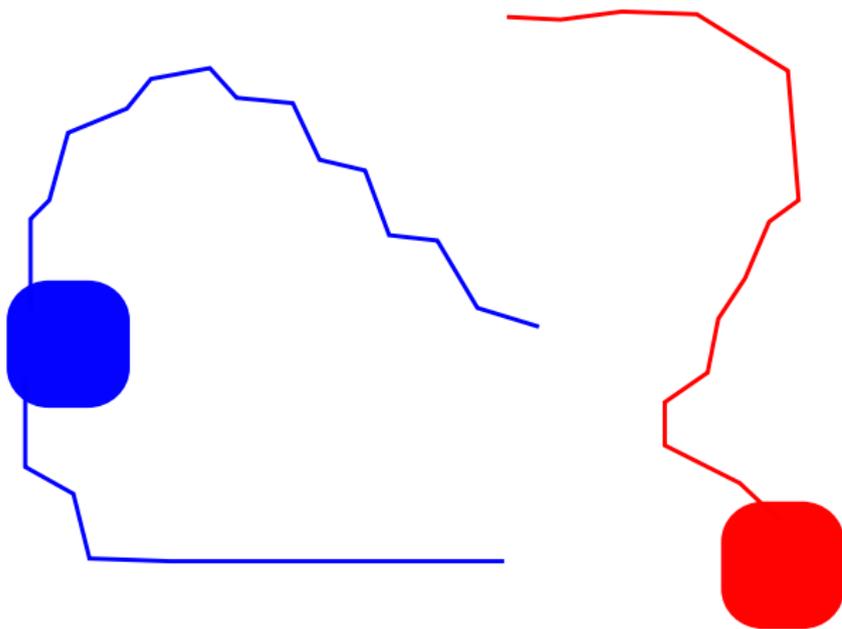

This is  $1/4$ -indecomposable.

## Theorem

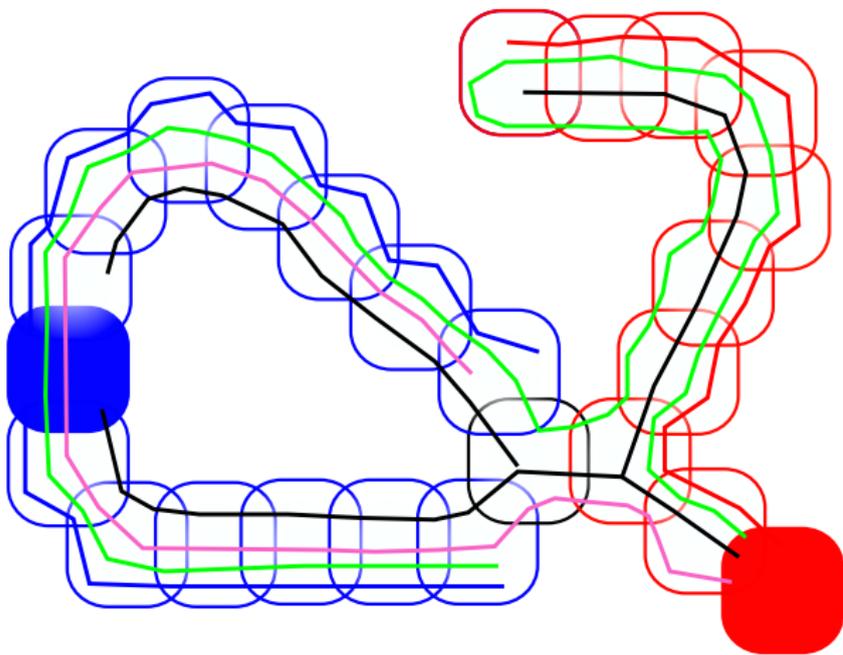

*Let  $X$  be a  $G$ -like continuum where  $G$  is a graph with  $m \geq 0$  cycles. If for every  $\varepsilon > 0$  there exists a collection  $\{A_1^\varepsilon, \dots, A_{m+2}^\varepsilon\}$  of pairwise disjoint subcontinua of  $X$  such that for each  $i$ ,  $d_H(A_i^\varepsilon, X) < \varepsilon$ , then  $X$  is semi-indecomposable.*

Suppose on the contrary that  $X$  has two disjoint subcontinua,  $H$  and  $K$ , that have nonempty interior. Let  $x_H \in \text{int}(H)$  and  $x_K \in \text{int}(K)$ . Then there exists  $0 < \varepsilon < (1/3)d(H, K)$  such that  $B_\varepsilon(x_H) \subset \text{int}(H)$  and  $B_\varepsilon(x_K) \subset \text{int}(K)$ . Let  $\mathcal{U}$  be an open cover of  $X$  with mesh less than  $\varepsilon$  and whose nerve is  $G$ .

Suppose on the contrary that  $X$  has two disjoint subcontinua,  $H$  and  $K$ , that have nonempty interior. Let  $x_H \in \text{int}(H)$  and  $x_K \in \text{int}(K)$ .

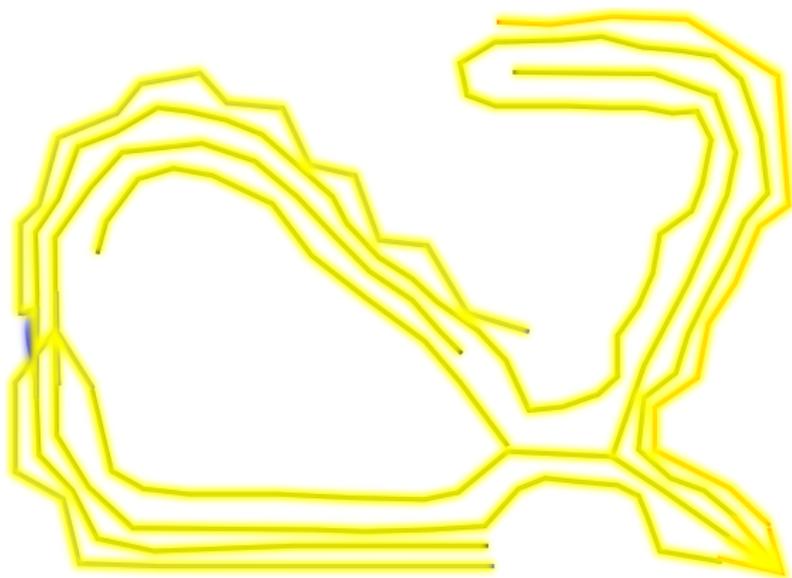

Let  $\lambda$  be a Lebesgue number for  $\mathcal{U}$ . By hypothesis, there exist disjoint subcontinua,  $A_1, A_2, A_3$ , such that  $d_H(X, A_i) < \lambda$  for each  $i$ .

Note that  $A_i \cap H \neq \emptyset$  and  $A_i \cap K \neq \emptyset$  for each  $i$ .

$A_i \cap H \neq \emptyset$  and  $A_i \cap K \neq \emptyset$  for each  $i$ .  
Let  $0 < \gamma < (1/3)d(A_i, A_j)$ ,  $i \neq j$ .

Let  $\mathcal{V}$  be any open cover with mesh less than  $\gamma$ . Then the nerve of this cover must have at least 3 circle-chains. This contradicts the fact that  $X$  is  $G$ -like (in this case 1-cyclic.)

## Lemma

*Let  $X$  be a  $G$ -like continuum where  $G$  is a graph with  $m \geq 0$  cycles. If there exists a mixing homeomorphism  $h : X \rightarrow X$ , then  $X$  must be  $\frac{1}{m+2}$ -indecomposable.*

Suppose to the contrary that  $X$  is not  $\frac{1}{m+2}$ -indecomposable, then there exists a collection  $\{A_1, \dots, A_{m+2}\}$  of pairwise disjoint subcontinua of  $X$  that have non empty interior. Let  $\varepsilon > 0$ . Then, since  $h$  is mixing, there exists an  $N$  such that for each  $i \in \{1, \dots, m+2\}$ ,  $d_H(h^N(A_i), X) \leq d_H(h^N(\text{int}(A_i)), X) < \varepsilon$ . Then the collection  $\{h^N(A_1), \dots, h^N(A_{m+2})\}$  satisfy the conditions of Theorem 6. Hence,  $X$  is semi-indecomposable and therefore  $\frac{1}{m+2}$ -indecomposable. This contradiction finishes the proof of the theorem.

Let  $X$  be a continuum. A collection of  $n$  subcontinua,  $\{A_i\}_{i=1}^n$ , is an  $n$ -decomposition for  $X$  if  $X = \bigcup_{i=1}^n A_i$ , but  $\bigcup_{i \neq j}^n A_i$  is a proper subset of  $X$  for each  $j$ .

A continuum  $X$  is  $n$ -indecomposable if there exists an  $n$ -decomposition but no  $(n + 1)$ -decomposition for  $X$ .

A 2-indecomposable continuum.

## Lemma

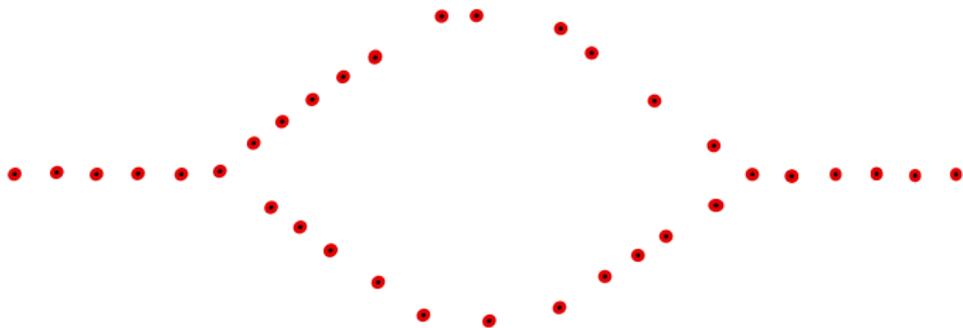

*If  $X$  is  $n$ -indecomposable, then there exists an  $n$ -decomposition into indecomposable subcontinua.*

Suppose that  $\{A_i\}_{i=1}^n$  is a  $n$ -decomposition of  $X$ . By Zorn's lemma, we may assume that  $\{A_i\}_{i=1}^n$  is a minimal decomposition. That is, if  $\widehat{A}_i$  is a proper subcontinuum of  $A_i$ , then  $\widehat{A}_i \cup \bigcup_{j \neq i} A_j \neq X$ . Suppose that  $A_i$  is decomposable. Then there exists proper subcontinua,  $A_i^1$  and  $A_i^2$ , such that  $A_i = A_i^1 \cup A_i^2$ . Then  $A_i^1 \cup \bigcup_{j \neq i} A_j \neq X$ ,  $A_i^2 \cup \bigcup_{j \neq i} A_j \neq X$  but  $A_i^1 \cup A_i^2 \cup \bigcup_{j \neq i} A_j = X$ . Hence,  $\{A_i^1, A_i^2\} \cup \{A_j\}_{j \neq i}$  is an  $(n+1)$ -decomposition. However, this contradicts the fact that  $X$  is  $n$ -indecomposable.

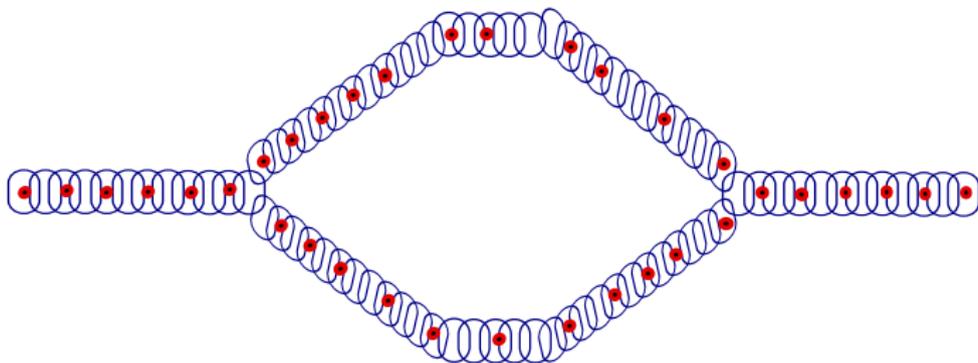

## Lemma

*Suppose that  $X$  is  $G$ -like and  $\frac{1}{n}$ -indecomposable. Then  $X$  is  $k$ -indecomposable for some  $1 \leq k \leq M$  with  $M = 2N(n+1) + r$ , where  $G$  is a graph with  $N$  maximal free arcs and  $r$  ramification points.*

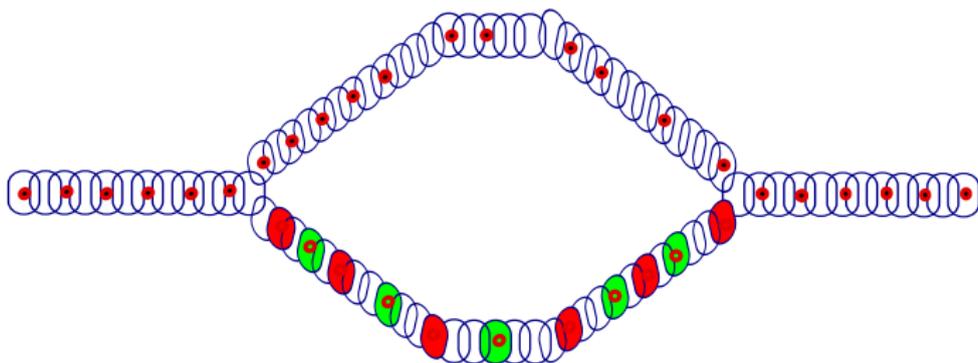

For example let  $N = 4$ ,  $r = 2$  and  $n = 3$  so  $M = 34$ . Suppose on the contrary that there exists a 35-decomposition  $\{A_i\}_{i=1}^{35}$ .

We may assume that there exists  $\epsilon > 0$  and  $a_i$  such that  $B_\epsilon(a_i) \subset A_i - \cup_{j \neq i} A_j$  for each  $i$ .

Let  $\gamma = \min d(a_i, A_j)$  for all  $i \neq j$ ,  $0 < \delta < (1/3) \min\{\epsilon, \gamma\}$  and  $\mathcal{U}$  be a  $G$ -cover with mesh less than  $\delta$ .

Then by the pigeon-hole principle, there exists a free chain that contains at least  $2(n + 1) = 8$  elements of our decomposition. However, that means that at least 4 must be pairwise disjoint. Since they all have nonempty interior this contradicts the assumption that the continuum is  $1/3$  indecomposable.

## Lemma

*Suppose that  $\{A_i\}_{i=1}^n$  is an  $n$ -decomposition of a  $G$ -like continuum  $X$  where each  $A_i$  is indecomposable. If  $h : X \rightarrow X$  is a homeomorphism, then for each  $i$  there exists an  $N_i$  such that  $h^{N_i}(A_i) = A_i$ .*

## Theorem

*Let  $X$  be a  $G$ -like continuum where  $G$  is a graph with  $m \geq 0$  cycles. If  $h : X \rightarrow X$  is a mixing homeomorphism, then  $X$  must be indecomposable.*

## Theorem

*Let  $X$  be a  $G$ -like continuum where  $G$  is a graph with  $m \geq 0$  cycles. If  $h : X \rightarrow X$  is a mixing homeomorphism, then  $X$  must be indecomposable.*

It follows from Lemmas 7 that  $X$  is  $1/j$ -indecomposable for some  $j$  and then 9 that  $X$  is  $k$ -indecomposable for some  $k$ . Hence it follows from Proposition 8 that there exists a  $k$ -decomposition,  $\{A_i\}_{i=1}^k$ , of  $X$  where each  $A_i$  is indecomposable. If  $k \geq 2$ , then  $A_1$  is a proper subcontinuum of  $X$  with nonempty interior. Hence, since  $h$  is mixing,  $d_H(h^n(A_1), X) \rightarrow 0$  as  $n \rightarrow \infty$ . However, it follows from Proposition 10 that there is an  $N$  such that  $h^N(A_1) = A_1$  for some  $N \neq 0$ . So  $d_H(h^{pN}(A_1), X) = d_H(A_1, X) > 0$  for all  $p$ . This contradicts the fact that  $h$  is mixing. Hence,  $X$  is indecomposable.

However, there exists a mixing homeomorphism on a hereditarily decomposable tree-like continuum!

However, there exists a mixing homeomorphism on a hereditarily decomposable tree-like continuum!

The universal dendrite  $D_\omega$ .

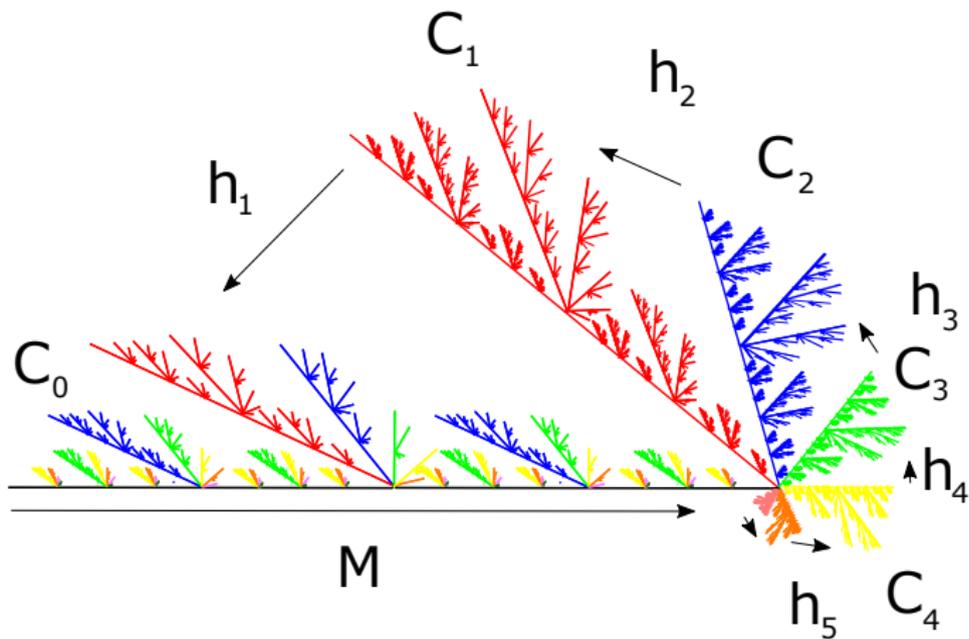

The dyadic universal dendrite.

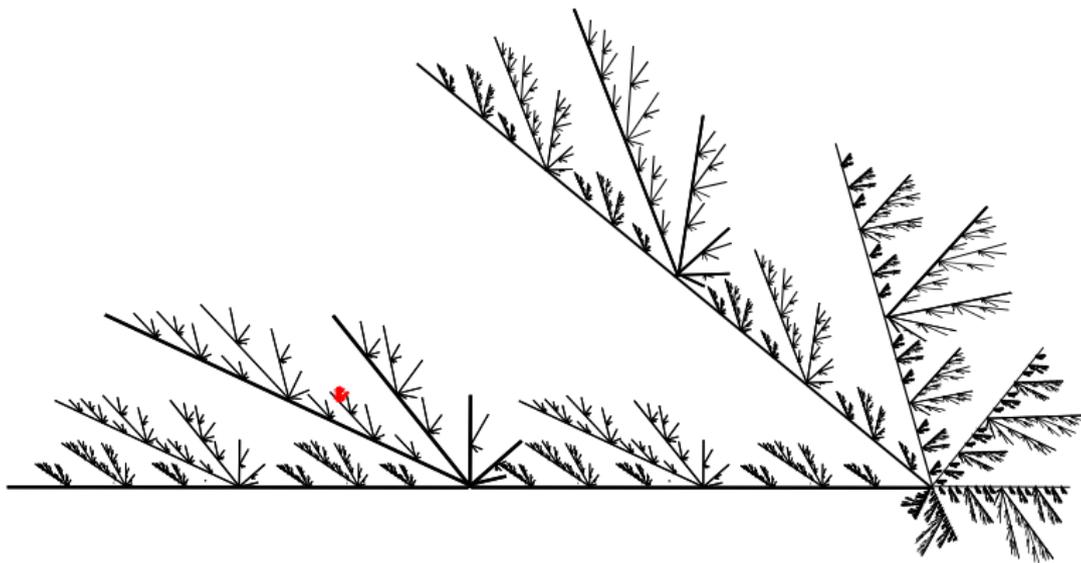

Each  $h_i : C_i \rightarrow C_{i-1}$  is a homeomorphism.

$M : C_0 \rightarrow \bigcup_{i=1}^{\infty} C_i$  is a local homeomorphism away from  $[0, 1]$ .

$g : D_\omega \rightarrow D_\omega$  by combining  $h_i$  and  $M$ .

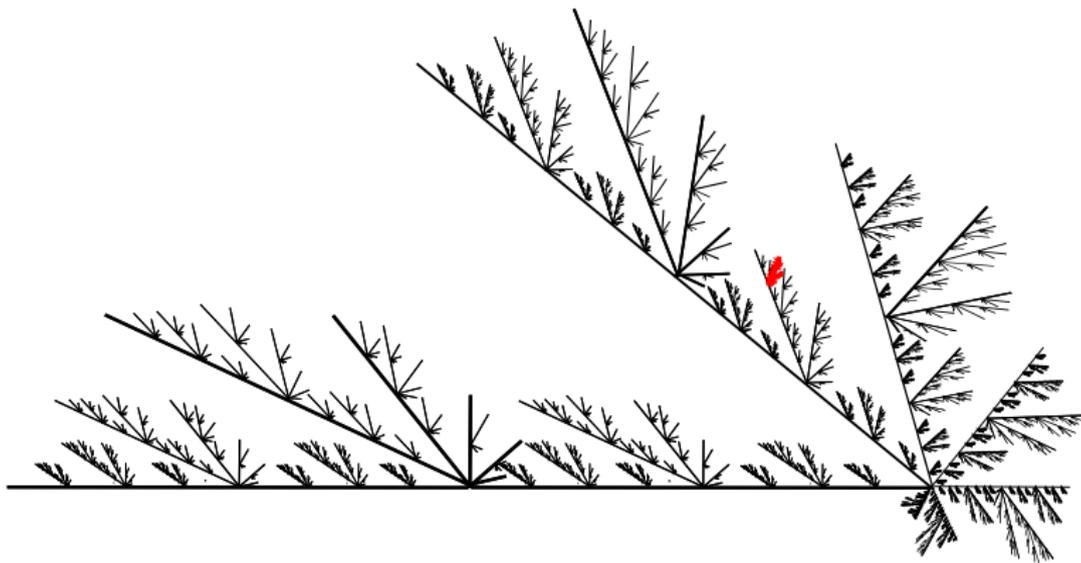

$g : D_\omega \longrightarrow D_\omega$  is mixing.

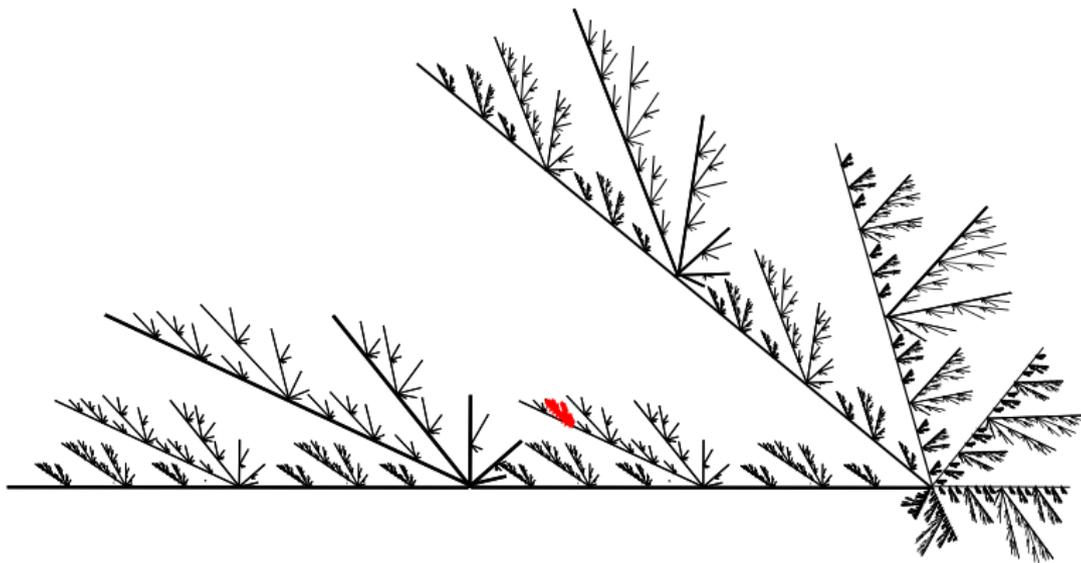

$g : D_\omega \longrightarrow D_\omega$  is mixing.

In fact it is also exact and weakly positively continuum-wise expansive.

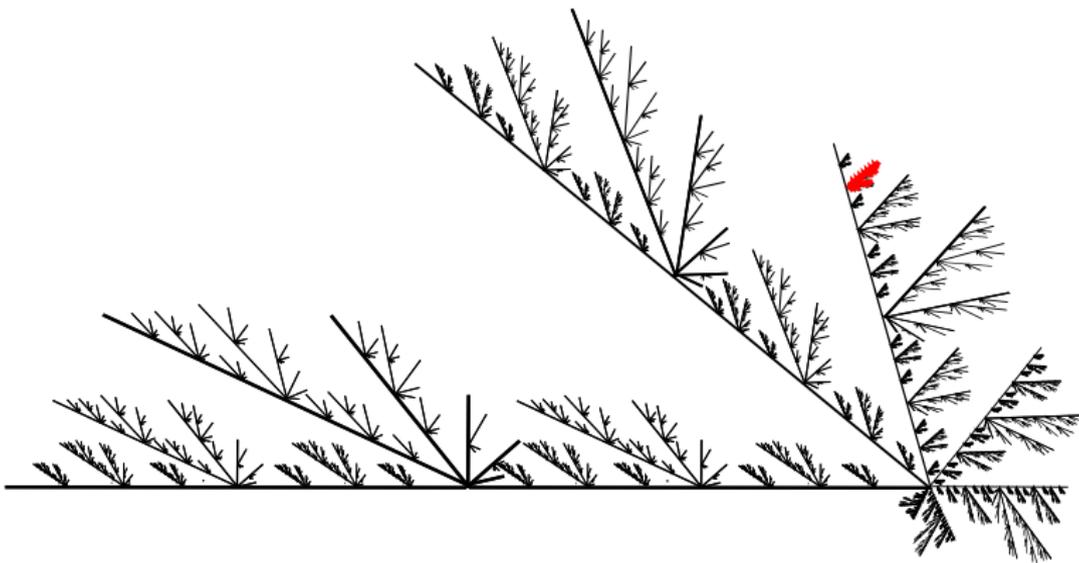

$g : D_\omega \longrightarrow D_\omega$  is mixing.

In fact it is also exact and weakly positively continuum-wise expansive.

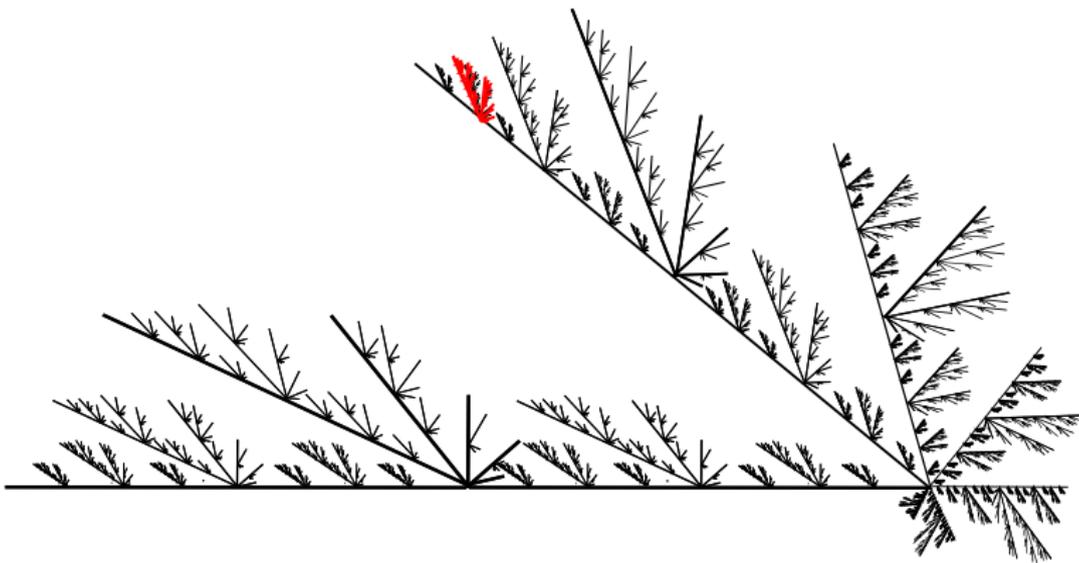

$g : D_\omega \longrightarrow D_\omega$  is mixing.

In fact it is also exact and weakly positively continuum-wise expansive.

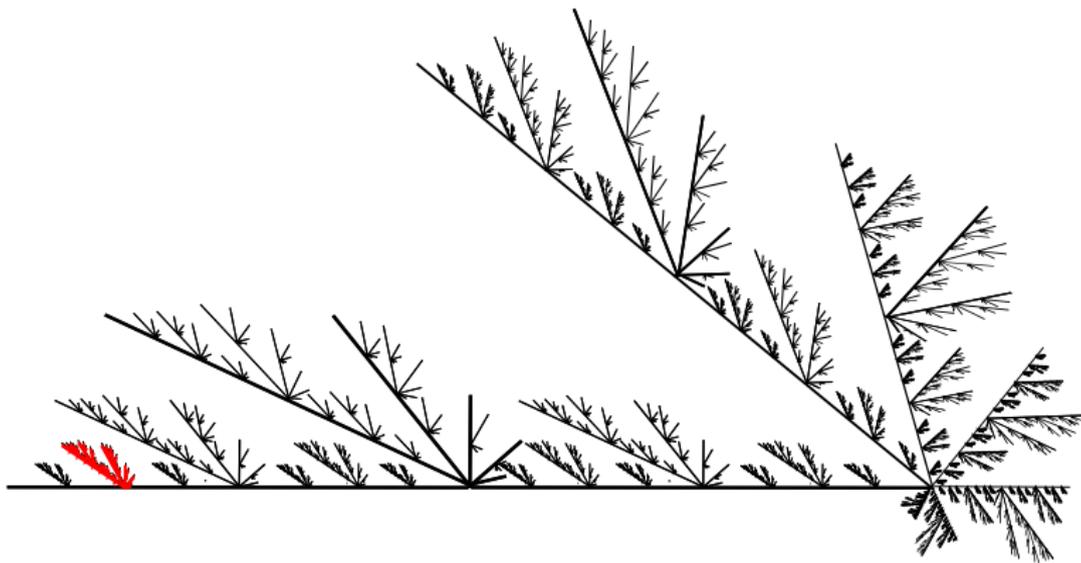

$g : D_\omega \longrightarrow D_\omega$  is mixing.

In fact it is also exact and weakly positively continuum-wise expansive.

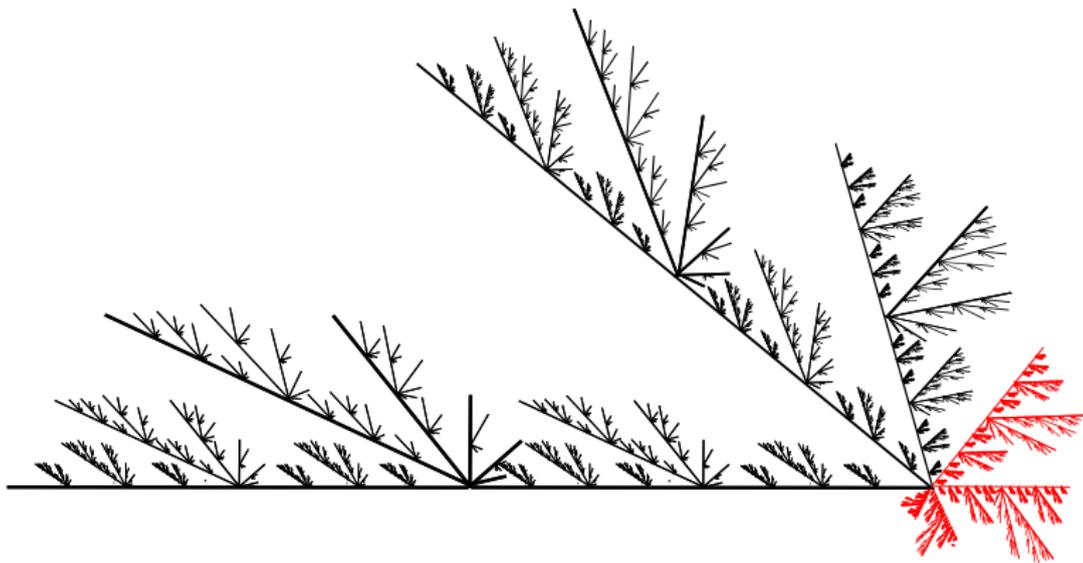

$g : D_\omega \longrightarrow D_\omega$  is mixing.

In fact it is also exact and weakly positively continuum-wise expansive.

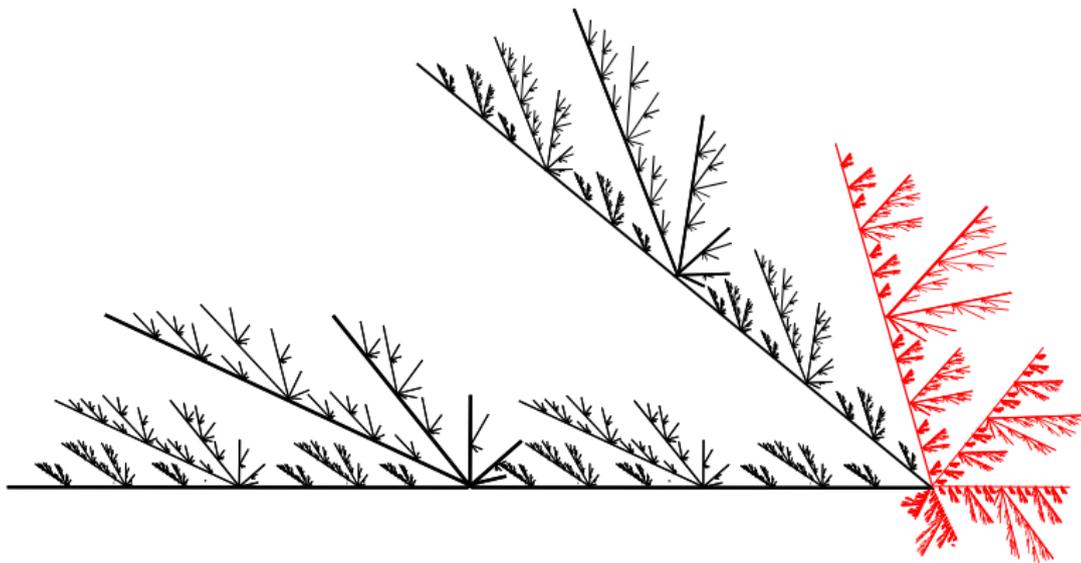

$g : D_\omega \longrightarrow D_\omega$  is mixing.

In fact it is also exact and weakly positively continuum-wise expansive.

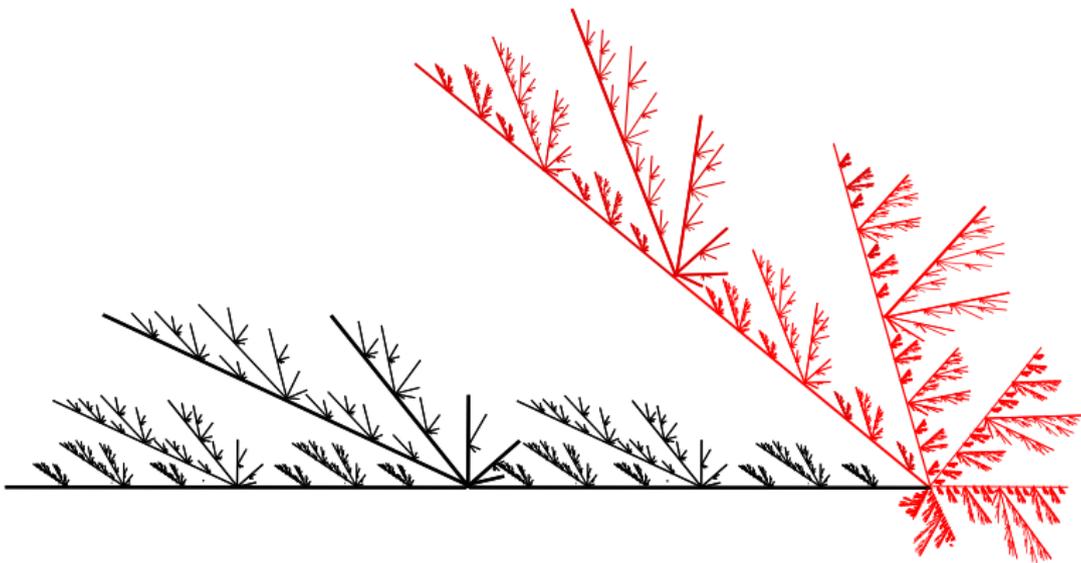

$g : D_\omega \longrightarrow D_\omega$  is mixing.

In fact it is also exact and weakly positively continuum-wise expansive.

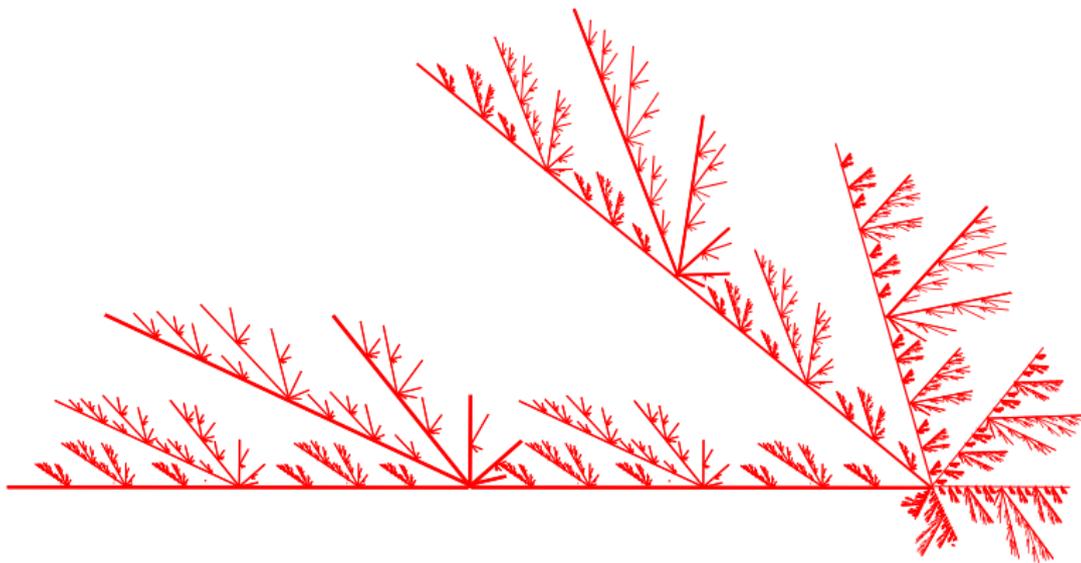

$g : D_\omega \longrightarrow D_\omega$  is mixing.

In fact it is also exact and weakly positively continuum-wise expansive.

$g : D_\omega \longrightarrow D_\omega$  is mixing.

In fact it is also exact and weakly positively continuum-wise expansive.

$g : D_\omega \longrightarrow D_\omega$  is mixing.

In fact it is also exact and weakly positively continuum-wise expansive.

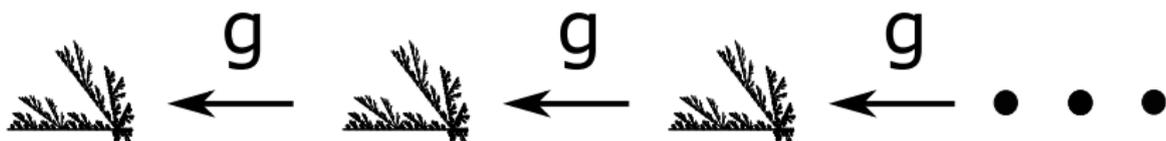

Let  $\widehat{D} = \varprojlim \{\widehat{D}_\omega, g\}_{n=1}^\infty$  be an inverse limit of universal dendrites.

Since  $g$  is mixing (weakly positively continuum-wise expansive), the shift homeomorphism  $\widehat{g}(\langle x_i \rangle_{i=1}^\infty) = \langle x_i \rangle_{i=2}^\infty$  is mixing (weakly positively continuum-wise expansive) .

Since dendrites are tree-like,  $\widehat{D}$  is tree-like.

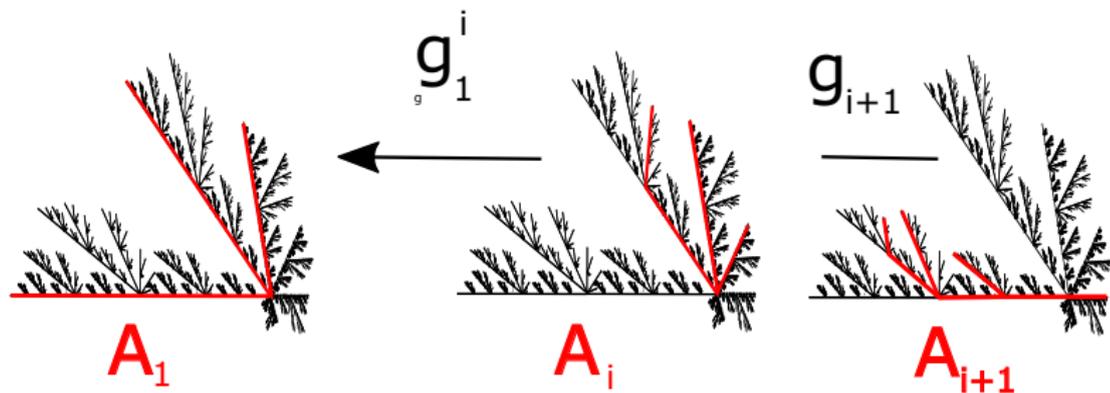

**Claim:**  $\widehat{D}$  is hereditarily decomposable.

Let  $\widehat{D} = \varprojlim \{\widehat{D}_\omega, g\}_{n=1}^\infty$  be an inverse limit of universal dendrites.

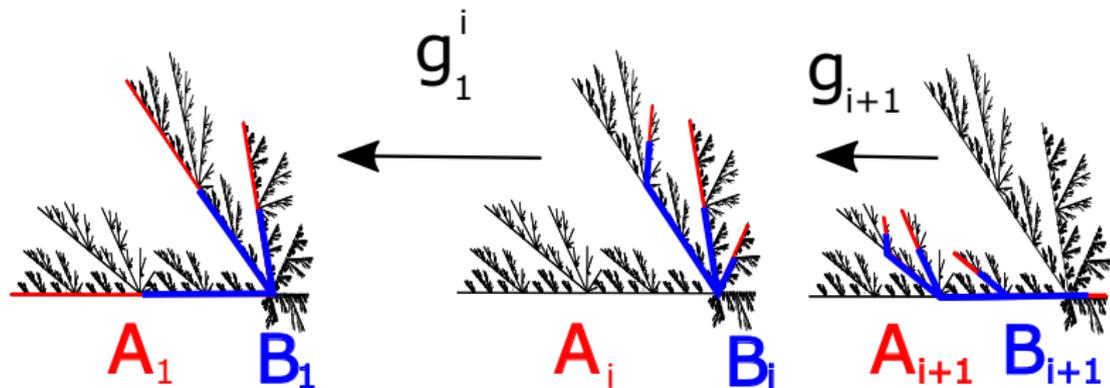

**Claim:**  $\widehat{D}$  is hereditarily decomposable.

**Proof** Let  $A$  be a subcontinuum of  $\widehat{D}$ . Then there exists subcontinua  $\{A_i\}_{i=1}^\infty$  of  $\widehat{D}$  such that  $A = \varprojlim \{A_i, g_i\}_{i=1}^\infty$  where  $g_i = g|_{A_{i+1}}$ .

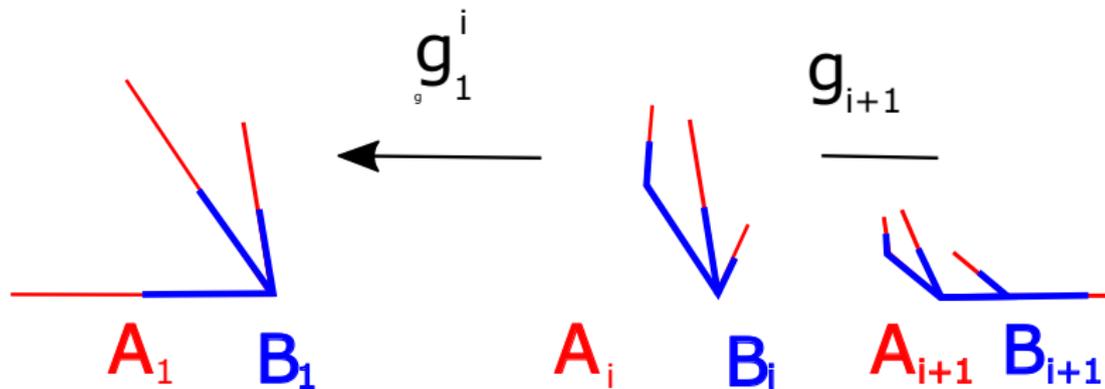

**Proof** Let  $A$  be a subcontinuum of  $\widehat{D}$ . Then there exists subcontinua  $\{A_i\}_{i=1}^{\infty}$  of  $\widehat{D}$  such that  $A = \varprojlim \{A_i, g_i\}_{i=1}^{\infty}$  where  $g_i = g|_{A_{i+1}}$ .

**Case 1** Suppose that  $0 \in A_i$  for every  $i$ .

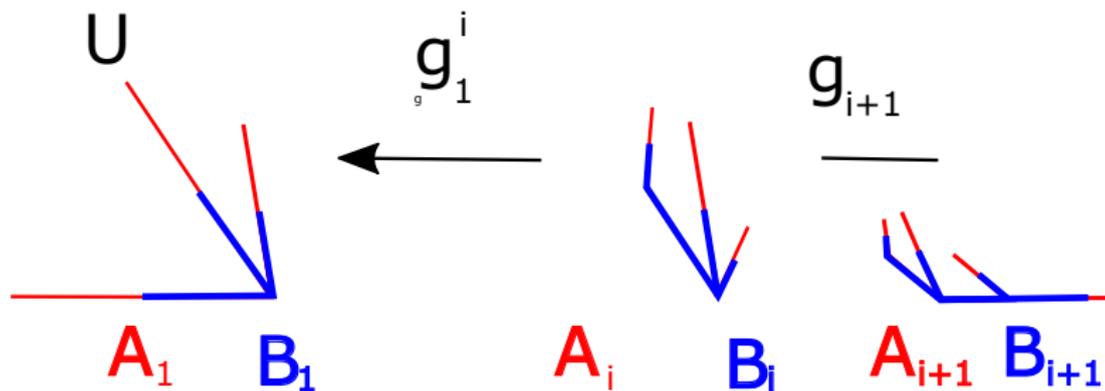

**Case 1** Suppose that  $0 \in A_i$  for every  $i$ .

Let  $B_1$  be a  $\bar{\alpha}$  proper subcontinuum of  $A_1$  such that  $0 \in \text{int}_{A_1}(B_1)$ .

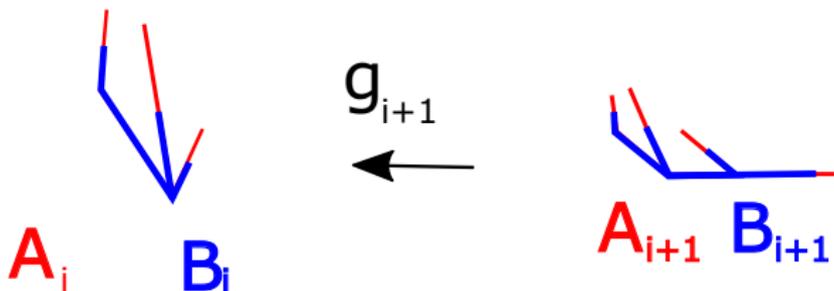

**Case 1** Suppose that  $0 \in A_i$  for every  $i$ .

Let  $B_1$  be a proper subcontinuum of  $A_1$  such that  $0 \in \text{int}_{A_1}(B_1)$ .

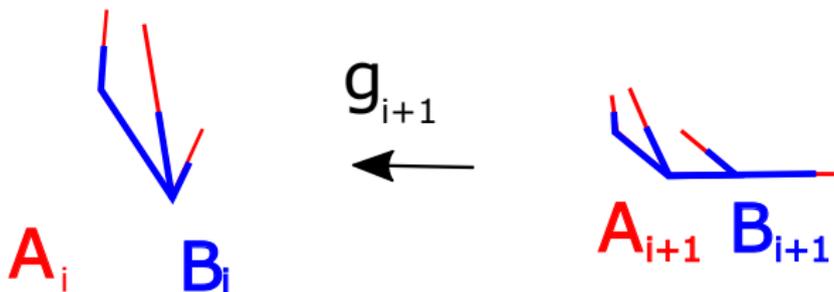

**Case 1** Suppose that  $0 \in A_i$  for every  $i$ .

Let  $B_1$  be a proper subcontinuum of  $A_1$  such that  $0 \in \text{int}_{A_1}(B_1)$  and  $U = A_1 - B_1$ . Let  $B_i$  be the component of  $A_i - (g_1^{i-1})^{-1}(U)$  that contains 0.

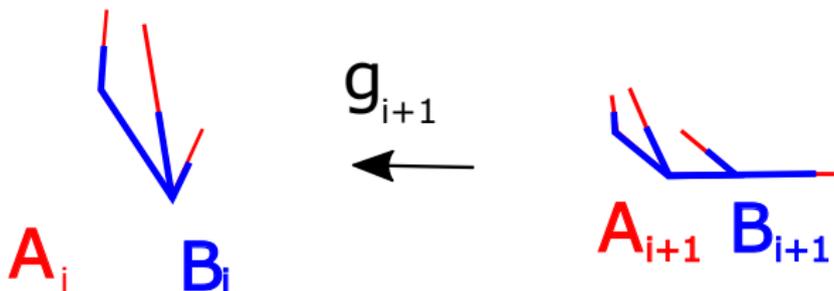

**Claim:**  $g_i^{-1}(B_i) = B_{i+1}$ .

It is clear that  $B_{i+1} \subset g_{i+1}^{-1}(B_i)$ . Let  $x \in g_{i+1}^{-1}(B_i)$  and  $[0, x]$  be the unique arc in  $A_{i+1}$  from 0 to  $x$ . Since  $g_{i+1}(x) \in B_i$  and  $B_i$  is uniquely arc-wise connected,  $g_{i+1}([0, x]) = [0, g_{i+1}(x)] \subset B_i$ . Since  $[0, g_{i+1}(x)] \cap (g_1^i)^{-1}(U) = \emptyset$ , it follows that  $[0, x] \cap (g_1^{i+1})^{-1}(U) = \emptyset$ . So  $[0, x] \subset B_{i+1}$  and it we get  $g_{i+1}^{-1}(B_i) = B_{i+1}$ .

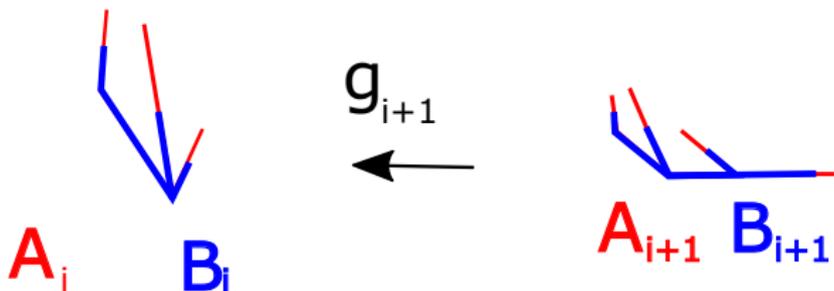

**Claim:**  $g_i^{-1}(B_i) = B_{i+1}$ .

It is clear that  $B_{i+1} \subset g_{i+1}^{-1}(B_i)$ . Let  $x \in g_{i+1}^{-1}(B_i)$  and  $[0, x]$  be the unique arc in  $A_{i+1}$  from 0 to  $x$ . Since  $g_{i+1}(x) \in B_i$  and  $B_i$  is uniquely arc-wise connected,  $g_{i+1}([0, x]) = [0, g_{i+1}(x)] \subset B_i$ . Since  $[0, g_{i+1}(x)] \cap (g_1^i)^{-1}(U) = \emptyset$ , it follows that  $[0, x] \cap (g_1^{i+1})^{-1}(U) = \emptyset$ . So  $[0, x] \subset B_{i+1}$  and it we get  $g_{i+1}^{-1}(B_i) = B_{i+1}$ .

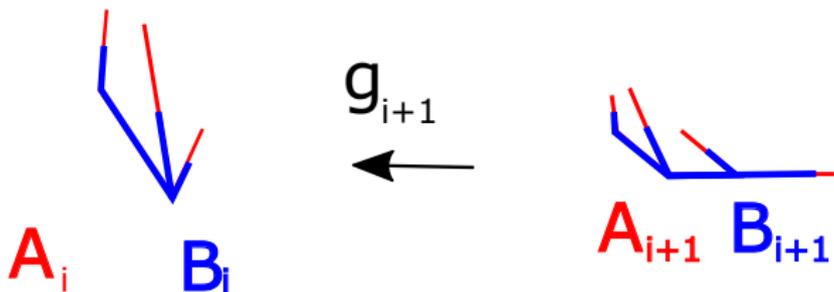

**Claim:**  $g_i^{-1}(B_i) = B_{i+1}$ .

Well if  $\widehat{D} = \varprojlim \{\widehat{D}_\omega, g\}_{n=1}^\infty$  isn't indecomposable what is it?

It is  $1/2$  indecomposable.

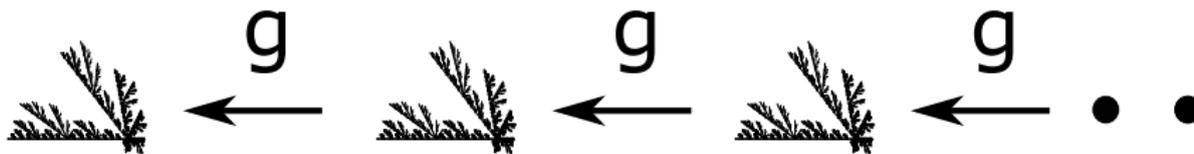

**Conjecture** If  $X$  is a one-dimensional continuum that admits a mixing homeomorphism, then  $X$  is  $1/n$  indecomposable for some  $n$ .

Well if  $\widehat{D} = \varprojlim \{\widehat{D}_\omega, g\}_{n=1}^\infty$  isn't indecomposable what is it?

It is  $1/2$  indecomposable.
