Mary Rees published a paper “A minimal positive entropy homeomorphism of the 2-torus” in 1980.

In that paper she gave a construction that allowed the modification of a minimal homeomorphism to suit her purposes. That construction was intricate and hard to understand, so in 2011, F. Béguin, S. Crovisier, and F. Le Roux wrote a 66-page paper, “Construction of curious minimal uniquely ergodic homeomorphisms on manifolds”, one of whose goals was to make the Rees construction more accessible.

Suppose we have a homeomorphism  $H : \mathbb{T}^2 \rightarrow \mathbb{T}^2$ .

By a *rectangle* we mean any subset of  $\mathbb{T}^2$  homeomorphic to the unit disc in  $\mathbb{R}^2$ .

Let  $\mathcal{E}, \mathcal{F}$  be a collection of rectangles. We say that  $\mathcal{F}$  refines  $\mathcal{E}$  if: (a) every element of  $\mathcal{E}$  contains at least one element of  $\mathcal{F}$ ; (b) for elements  $X \in \mathcal{E}$ ,  $Y \in \mathcal{F}$  either  $X \cap Y = \emptyset$  or  $Y \subset \text{int } X$ . We define

$$\text{mesh } \mathcal{E} = \max\{\text{diam } X : X \in \mathcal{E}\}.$$

## $p$ -times iterable

Let  $p \in \mathbb{N}$ . A collection of rectangles  $\mathcal{E}$  is  $p$ -times iterable if for rectangles  $X, Y \in \mathcal{E}$  and integers  $-p \leq k, s \leq p$ , either  $H^k(X) = H^s(Y)$  or  $H^k(X) \cap H^s(Y) = \emptyset$ . For any  $p$ -times iterable family of rectangles  $\mathcal{E}$  and any  $0 \leq n \leq p$ ,

$$\mathcal{E}^n = \bigcup_{|k| \leq n} H^k(\mathcal{E}),$$

where as usual  $H(\mathcal{E}) = \{H(X) : X \in \mathcal{E}\}$ . In particular,  $\mathcal{E}^0 = \mathcal{E}$ . Given an integer  $0 \leq n \leq p$  we define an oriented graph  $G = G(\mathcal{E}^n)$ , where the vertices are elements of  $\mathcal{E}^n$  and there is an edge from  $X$  to  $Y$  provided that  $H(X) = Y$ . For  $n < p$  we say that  $\mathcal{E}^n$  has no cycle if the graph  $G(\mathcal{E}^n)$  has no cycle.

## $\mathcal{F}$ is compatible with $\mathcal{E}$ for $p$ iterates

For a collection of rectangles  $\mathcal{E}$ , let us denote by  $\mathfrak{s}(\mathcal{E})$  the union of all rectangles in  $\mathcal{E}$ . Fix an integer  $p \geq 0$  and let  $\mathcal{E}, \mathcal{F}$  be collections of rectangles such that  $\mathcal{E}$  is  $p$ -times iterable and  $\mathcal{F}$  is  $(p+1)$ -times iterable. Assume additionally that  $\mathcal{F}^{p+1}$  refines  $\mathcal{E}^p$ . If for every  $k$  such that  $|k| \leq 2p+1$ , we have  $H^k(\mathfrak{s}(\mathcal{F})) \cap \mathfrak{s}(\mathcal{E}) \subset \mathfrak{s}(\mathcal{F})$ , then we say that  $\mathcal{F}$  is compatible with  $\mathcal{E}$  for  $p$  iterates.

Now we are ready to state the main axioms which are the building blocks in the construction. Let  $(\mathcal{E}_n)_{n \in \mathbb{N}_0}$  be a sequence of collections of rectangles. We introduce the following hypotheses:

**A<sub>1</sub>** : For every  $n \in \mathbb{N}_0$

**a<sub>n</sub>** : the collection  $\mathcal{E}_n$  is  $(n + 1)$ -times iterable and  $\mathcal{E}_n^n$  has no cycle;

**b<sub>n</sub>** : the collection  $\mathcal{E}_n^{n+1}$  refines the collection  $\mathcal{E}_m^{m+1}$  for every  $0 \leq m < n$ ;

**c<sub>n</sub>** : the collection  $\mathcal{E}_{n+1}$  is compatible with  $\mathcal{E}_n$  for  $n + 1$  iterates.

**A<sub>3</sub>** :  $\lim_{n \rightarrow \infty} \text{mesh } \mathcal{E}_n^n = 0$ .

# the homeomorphisms $M_i$

Oprocha

Assume that  $(M_n)_{n \in \mathbb{N}}$  is a sequence of homeomorphisms  $M_n: \mathbb{T}^2 \rightarrow \mathbb{T}^2$  and that for every  $n$  the homeomorphisms  $\Psi_n, g_n$  are defined by:

$$\begin{aligned}\Psi_n &= M_n \circ \dots \circ M_2 \circ M_1, \\ g_n &= \Psi_n^{-1} \circ H \circ \Psi_n.\end{aligned}$$

Finally we set  $\Psi_0 = \text{id}$ ,  $g_0 = H$ .

# More conditions on the $M_n$

How to tinker

morphism and  
get away with  
it

Judy Kennedy  
Joint work  
with Jan  
Boronski,  
Xiaochuan Liu  
and Piotr  
Oprocha

In addition, assume that the homeomorphisms  $M_n$  satisfy the conditions specified below:

**B<sub>1</sub>** : For every  $n \in \mathbb{N}_0$ :

**B<sub>1,n</sub>** : The support of the homeomorphism  $M_n$  is contained in the set  $\mathcal{E}_{n-1}^{n-1}$ , where as usual the support of the homeomorphism  $M_n$  is defined by  $\text{supp } M_n = \overline{\{x : M_n(x) \neq x\}}$ .

**B<sub>2</sub>** : For every  $n \in \mathbb{N}_0$ :

**B<sub>2,n</sub>** : The homeomorphisms  $M_n$  and  $H$  commute along edges of the graph  $G(\mathcal{E}_{n-1}^{n-1})$ .

**B<sub>3</sub>** : Denote  $\mathcal{A}_n = \mathcal{E}_n^{n+1} \setminus \mathcal{E}_n^{n-1}$  for every  $n \in \mathbb{N}_0$ .

**B<sub>3,n</sub>** : The mesh  $\{\Psi_{n-1}^{-1}(X) : X \in \mathcal{A}_n\} < 1/n$ ;  
and, in particular,

$$\lim_{n \rightarrow \infty} \text{mesh}\{\Psi_{n-1}^{-1}(X) : X \in \mathcal{A}_n\} = 0.$$

The following fact is [BCL, Proposition 3.1]. It ensures proper convergence of the constructed functions.

## Lemma

*Assume that hypotheses  $\mathbf{A}_{1,3}$ ,  $\mathbf{B}_{1,2,3}$  are satisfied. Then:*

- 1** *The sequence of homeomorphisms  $(\Psi_n)_{n \in \mathbb{N}}$  converges uniformly to a continuous surjective map  $\Psi: \mathbb{T}^2 \rightarrow \mathbb{T}^2$ .*
- 2** *The sequence of homeomorphisms  $(g_n)_{n \in \mathbb{N}}$  converges uniformly to a homeomorphism map  $g: \mathbb{T}^2 \rightarrow \mathbb{T}^2$  and  $(g_n^{-1})_{n \in \mathbb{N}}$  converge uniformly to its inverse  $g^{-1}$ .*
- 3** *The homeomorphism  $g$  is an extension of  $H$  by  $\Psi$ , that is,  $H \circ \Psi = \Psi \circ g$ .*

The following is Proposition 3.4 in BCL.

## Lemma

Let  $K = \bigcap_{n \in \mathbb{N}} \mathfrak{s}(\mathcal{E}_n)$  and assume that hypotheses  $\mathbf{A}_{1,3}$ ,  $\mathbf{B}_{1,2,3}$  are satisfied.

- 1 Fix  $x \in \mathbb{T}^2$  and suppose that there is  $m \in \mathbb{Z}$  such that  $x \in H^m(K)$ . Let  $(X_n)_{n \geq m}$  be the decreasing sequence of rectangles in  $\mathcal{E}_n^m$  containing  $x$ . Then

$$\Psi^{-1}(x) = \bigcap_{n \geq m} \Psi_n^{-1}(X_n).$$

- 2 For every  $x$  which does not belong to the orbit of  $K$  the set  $\Psi^{-1}(x)$  is a single point.

# minimal noninvertible pseudocircle map

How to tinker

We wish to construct a minimal map on the pseudocircle which is not a homeomorphism. The main step of the construction is the following theorem. We denote the annulus by  $\mathbb{A}$ .

## Theorem

*There exists a homeomorphism  $g: \mathbb{A} \rightarrow \mathbb{A}$  with an invariant pseudocircle  $P \subset \mathbb{A}$  such that  $(g, P)$  is minimal and there exists a pseudoarc  $A \subset P$  such that  $\lim_{|n| \rightarrow \infty} \text{diam } g^n(A) = 0$ .*

with Jan  
Boronski,  
Xiaochuan Liu  
and Piotr  
Oprocha

- Let  $H: \mathbb{A} \rightarrow \mathbb{A}$  be the annulus homeomorphism defined by Handel. In particular, (1)  $H$  is a rotation on (both) circles that form the boundary of  $\mathbb{A}$ , (2) there exists an essential pseudocircle  $P \subset \mathbb{A}$  that is a minimal, invariant subset under  $H$ , and (3) every point from the interior of  $\mathbb{A}$  is attracted by  $P$ .
- We can “glue” the boundary of  $\mathbb{A}$  to a single circle, call it  $S$ , which turns  $\mathbb{A}$  into  $\mathbb{T}^2$ , and now (our modified)  $H: \mathbb{T}^2 \rightarrow \mathbb{T}^2$ . If we perturb  $H$  to a homeomorphism  $H'$  in such a way that  $H$  and  $H'$  coincide in a neighborhood of  $S$ , then we can again “cut back”  $\mathbb{T}^2$  to  $\mathbb{A}$  obtaining a well defined homeomorphism  $H': \mathbb{A} \rightarrow \mathbb{A}$ .
- In particular, if, in a sufficiently small neighborhood of  $P$  there is an  $H'$ -invariant set  $P'$ , which is a hereditarily indecomposable circlelike continuum, then it must also be a pseudocircle.

**Step 1. Definition of the maps  $M_n$ .** To start the construction, fix a pseudoarc  $A \subset P$  and a point  $p \in A$ . There exists a sequence of rectangles  $(U_n)_{n \in \mathbb{N}}$ ,  $U_{n+1} \subset \text{int } U_n \subset \mathbb{T}^2$  such that  $\bigcap_{n \in \mathbb{N}} U_n = A$ . There also exists a decreasing sequence of rectangles  $(V_n)_{n \in \mathbb{N}}$  such that (1)  $V_n \subset U_n$  for each  $n$ , (2)  $p \in \text{int } V_n$  for every  $n$ , and (3)  $\bigcap V_n = \{p\}$ . The pseudocircle  $P$  is an invariant set of  $H$  without fixed points, the pseudoarcs  $H^i(A)$  belong to different composants of  $P$  for different  $i \in \mathbb{Z}$ . In particular  $H^i(A) \cap H^j(A) = \emptyset$  for  $i \neq j$ , hence we may assume that for  $|i| \leq 3n$  the sets  $H^i(U_n)$  are pairwise disjoint. Furthermore, we may assume that  $\text{diam } H^i(V_n) < \frac{1}{n+1}$  for  $|i| \leq 3n$ . Since the pseudoarc  $A$  can be chosen to be arbitrarily small, we may assume that  $V_0 = U_0$ . Let  $\mathcal{E}_0 = \{V_0\}$ . Take any  $k_1 > 2$  and let  $M_1: \mathbb{T}^2 \rightarrow \mathbb{T}^2$  be a homeomorphism such that  $M_1|_{U_1}$  is a homeomorphism between  $U_1$  and  $V_{k_1}$  and  $M_1|_{\mathbb{T}^2 \setminus \text{int } U_0} = \text{id}$ . Require additionally that  $M_1(p) = p$ .
