ABSTRACT. In this paper we introduce the class of π -pseudocomplete spaces, which contains the class of π -complete spaces. Among others, we show that assuming $\text{MA}+\neg\text{CH}$, π -pseudocomplete CCC spaces satisfy the strong Baire property and π -pseudocomplete CCC spaces with small pseudobases are separable (Theorem 3.12 and Theorem 4.2, respectively). Finally, we prove, also assuming $\text{MA}+\neg\text{CH}$, that if X is a T_1 quasiregular compact space with $c(X) = \omega$, $t(X) = \omega$ and $|\text{cl}_X(A)| \leq 2^\omega$ for every $A \in [X]^{\leq \omega}$, then $|X| \leq \text{HW}(X)2^\omega$ (Corollary 4.17). This result provides a partial positive answer to the following question due to Arhangel'skii ([1]): Does $\text{MA}+\neg\text{CH}$ imply that every compact space with $c(X) = \omega$ and countable tightness has cardinality $\leq 2^\omega$?

1. INTRODUCTION

A topological space X has countable cellularity (or X is CCC), denoted by $c(X) \leq \omega$, if every disjoint family of open sets in X is at most countable. It is well known that Martin's Axiom (MA) with the negation of the Continuum hypothesis ($\neg\text{CH}$) imply the Suslin hypothesis, that is, every ordered space with countable cellularity is separable.

The following question posed by Hajnal and Juhász, is natural (see [10]).
