## Correspondence between Critical Portraits and Weakly Bicolored Trees

David George (University of Alabama, Birmingham) dgeorge@uab.edu

Abstract: Critical portraits can be represented by weakly bicolored trees. Weakly bicolored trees are comprised of  $\mathbf{P}$  and  $\mathbf{F}$  nodes.  $\mathbf{P}$  nodes represent regions with a non-zero rotation.  $\mathbf{F}$  nodes represent regions that contain fixed points.  $\mathbf{F}$  nodes may be adjacent to other  $\mathbf{F}$  nodes, but  $\mathbf{P}$  nodes may not be adjacent to other  $\mathbf{P}$  nodes. For degree d, a unit disk with a maximal number of non-crossing chords of critical length (each length k/d for some k) that can only meet at endpoints is called a critical portrait. One can easily map from a critical portrait to a corresponding tree in a fashion that is complete and unambiguous. The interesting cases arise when mapping from a tree to a corresponding critical portrait. Only in the case of trees which are fans do we have a correspondence that is one-to-one. Other weakly bi-colored trees can only be mapped to families of critical portraits since their correspondence is not one-to-one. We explore possible bounds on the number of portraits in these families based on the number of edges on a tree.
